

Useful Methods for Processing N-dimensional X-ray Datacubes

A Volcanological Example

Ed Vicenzi

*Department of Mineral Sciences
Washington, DC*

Outline

- ✓ Concept of localized bulk chemistry on the microscale
- ✓ Introduction to MVS, the spatial simplicity method, and paths to chemical phase analysis
- ✓ The tale of Parícutin Volcano
- ✓ Phase results from Parícutin specimens

Microscope: FEI Nova NanoSEM600 an FE-VP SEM
X-ray detector: Si(Li)/40 mm²/ThermoFisherSci-Nanotrace
Analyzer: NSS 300
Software: NSS v2/Compass (AXSIA)/X Phase

Ultimate Analytical Objectives

- Measure area (volume) fraction of all chemical phases present
- Measure composition of all phases of interest (POI)
- Normalize volume fractions and weight phase microchemistry accordingly

Sounds simple! and leads to the determination of a sample's **Local Bulk Chemistry (LBC)**

Local Bulk Composition?

Determination of the chemical nature of a sub-volume of a sample. It often yields information about the specimen's history e.g. by way of comparison with bulk properties

Traditional approaches

- Estimate area fractions by segmenting BSE image, perform representative point analyses of each POI **Fraught with problems**
- Analyze sum raster **Fahgetaboutit!**

Ideal approach

Base area estimate on segmentation of 10^3 - 10^4 X-ray analyses. POI composition from aggregate of spectra at all locations, yielding improved statistics

Some Applications

Earth Sciences

- reconstruction of trapped liquid composition in complex melt inclusions (eg w/daughter crystals)
- crystal- melt geothermometry where glass composition is not accessible owing to groundmass crystallization (element partitioning in general)
- estimation of fluid chemistry by summing all precipitated material in a vein

Materials Sciences

- heterogeneity of welds

The Hyperspectral Data Cube

Hyperspectral \equiv more than 20 spectral bands

measured at SI

Feature of
exceptional
interest

chemical
information

Wavelength resolved UV-VIS

Energy resolved X-rays

Mass resolved ions

Simplification of the Data Cube Prior to Computing the LBC

Spatial Weighting of All Elements in Each Phase

$$\sum EI_{1 \rightarrow n} * A_{\text{phase}_{1 \rightarrow n}}$$

where:

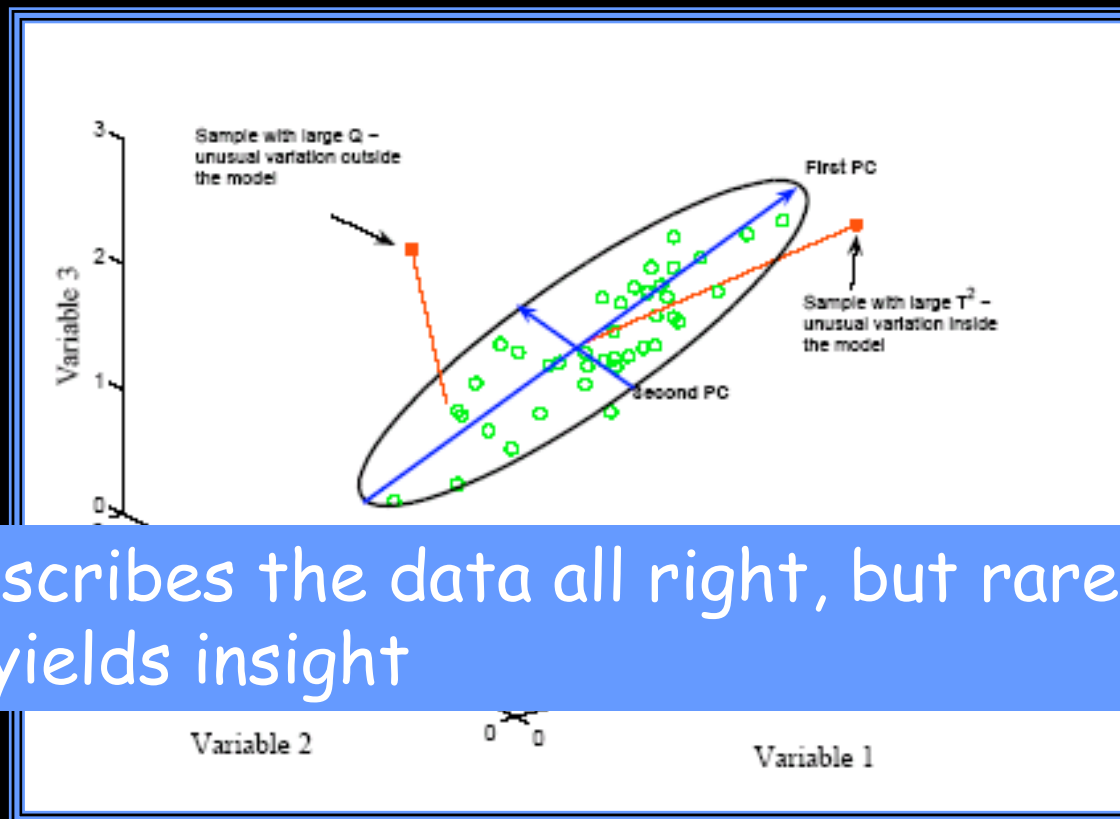

A_{phase} = area fraction

EI_n = elemental concentration

Method I: Mining Hyperspectral Datasets in N-Dimensional Compositional Space

Traditional Factor Analysis: Classical Principal Components

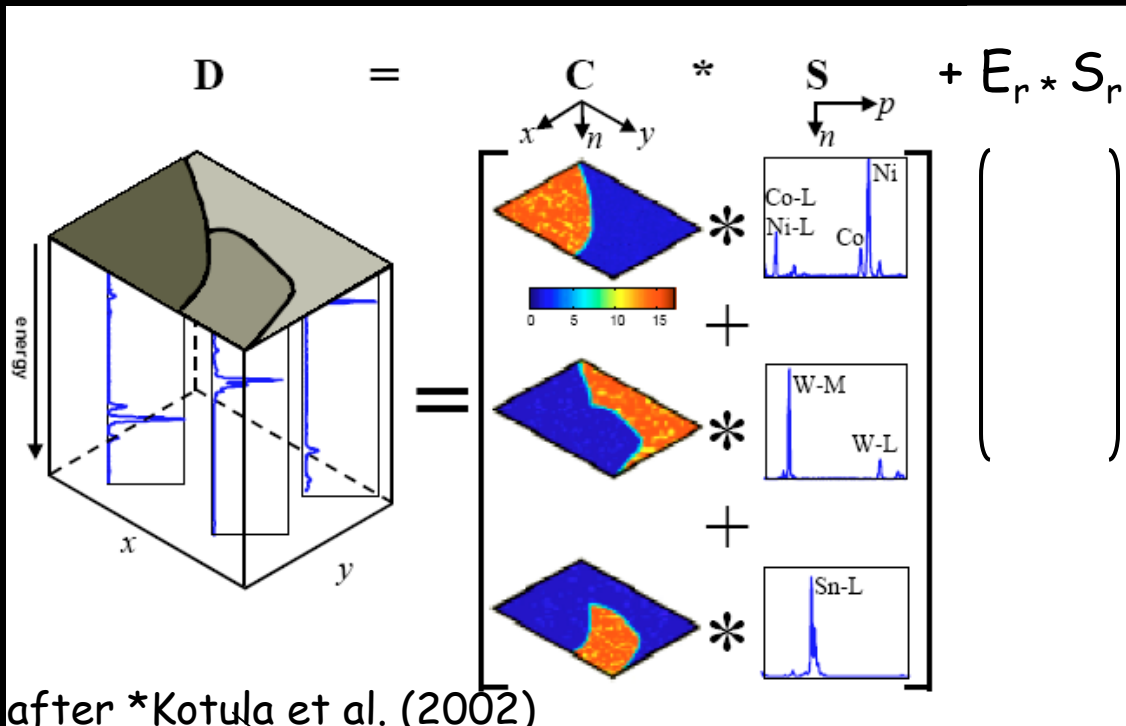

Describes the data all right, but rarely yields insight

The Alternate Approach of Keenan & Kotula

Spatial or Spectral Simplicity Solutions

An infinite # solutions possible (rotational ambiguity) in N dimensions. We seek only those that give us insight.

Spectral simplicity*

High spectral contrast solution.

Spatial simplicity

High spatial contrast solution.

Spatial Simplicity (Keenan and Kotula, unpublished)

- $D = CS^T$ (Goal: Factor raw data into C and S ...linear model)
 - D is an m -pixel \times n -channel raw spectral-data matrix
 - S is an $n \times p$ matrix containing the p pure-component spectra shapes
 - C is an $m \times p$ matrix containing their spatial distributions/abundances
- Data is scaled to account for non-uniform (Poisson) noise*
 - Allows for noise on signals of all levels to be accounted for
- PCA is performed on the scaled data such the the **spatial** components are orthonormal
 - Instead of classical PCA (max variance in spectral domain), maximize variance in the spatial domain.
- Rotate the **spatial** components to maximize their mutual simplicity with the VARIMAX procedure
 - Rotate PCA_{sp} solution in N dimensions to obtain maximum # zeros in one dimension of the matrix.

*M.R. Keenan and P.G. Kotula, *Surf. Int. Anal.* 36 (2004) 203-212.

Spatial Simplicity (contin.)

- Apply the inverse rotation to the spectral components

Necessary to maintain the product [$C \times S$]

Note: The VARIMAX solution fits the data as well as the PCA solution, however yields more physical insight into the specimen by virtue of the assumption that simplicity is desirable and defined as maximized contrast.

- Perform non-negativity-constrained *classical* least squares (CLS) on the data, making *spatial* components all positive

D (known) = C (constrained) $\times S$

Hence, set all neg. values for C to 0 and solve for S accordingly

- Inversely scale the components for Poisson noise

Restores normalized count space back to real count space

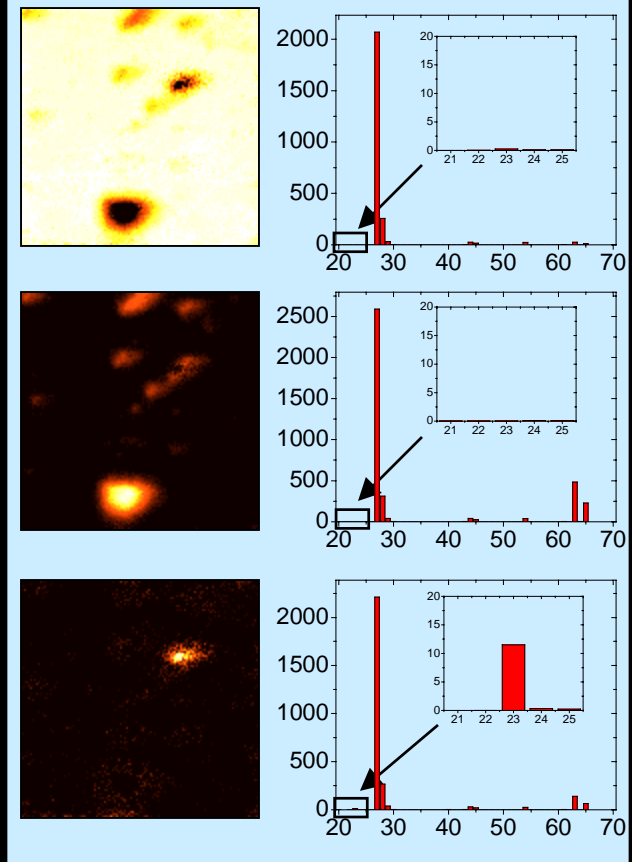

Rotated PCA Delivers a Spatially Simple Analysis

Rotated PCA

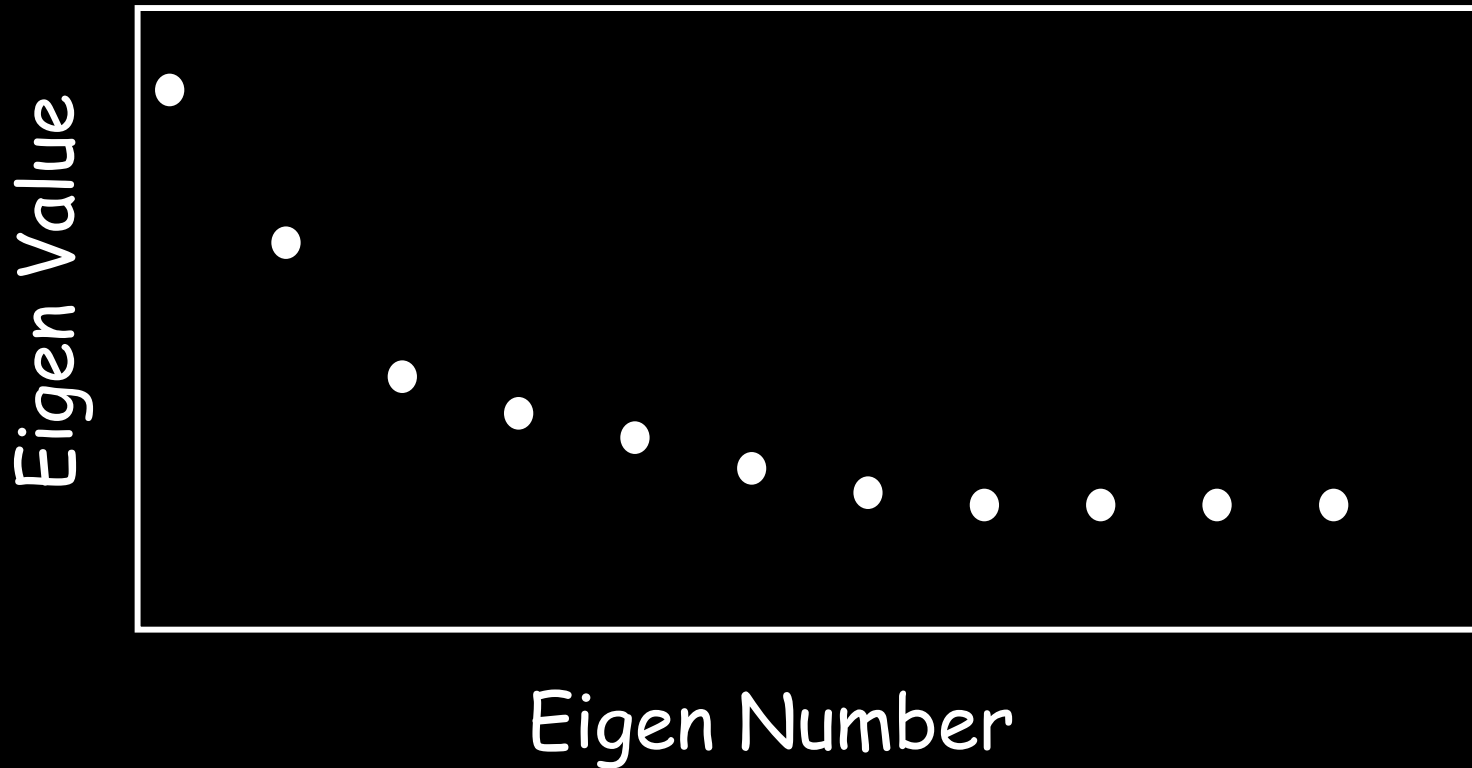

- Based on a Varimax rotation of PCA images
- Relaxes orthogonality of one dimension
 - Separates data based on simplifying images or spectra
 - Works well with data containing large spectral backgrounds (AES, XPS)
- Minor spectral features can be hard to find.

Q. Where is the spatial contrast in the image, and what is it?

Spatially Simple Rotation

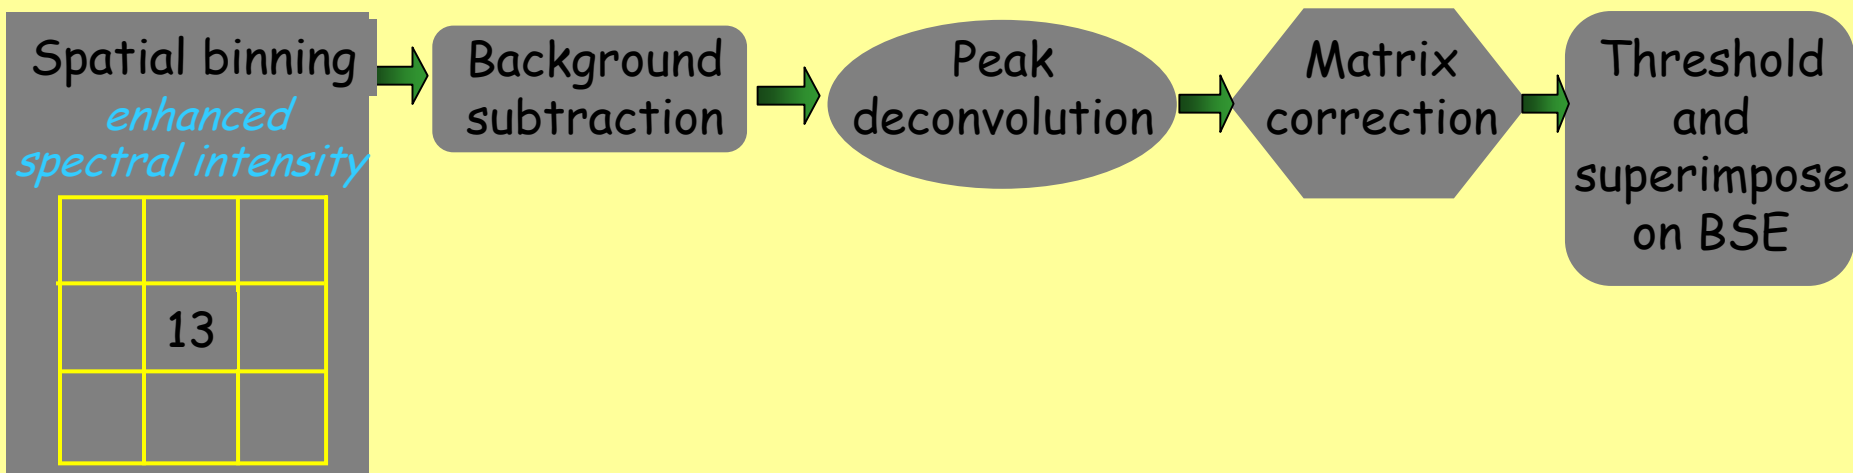

How Many MVS Components will Describe My Data?

Keenan-Kotula assume no more than 25 components

Method II: Elemental Maps & Quantified Spectral Images

Paths to Phase Analysis

Simplification of
data cube

Compute MVS spatial
simplicity solution
(mathematical result)

Compute quantified
X-ray images usually
spatially binned

Segmentation into
chemical phases

Perform X Phase[†]

Perform X Phase[†]

Quant

Quantify aggregate
pixels for each phase

Quantify aggregate
pixels for each phase

[†]X Phase output: Binary masks showing location of
phases and associated spectra (real data)

Phase Segmentation:

X Phase

Input: **Compass** (Spectral/Spatial simplicity) results,
or, **X-ray images** (raw cts. or quantified)

- Define min area for a phase (default = 1.5%)
- Perform histogram stretch on each image
- Multiply each image by the others, and stretch resulting 16 bit image
- Threshold image and binarize
- If mask is $>1.5\%$ of tot. area, declare it a phase

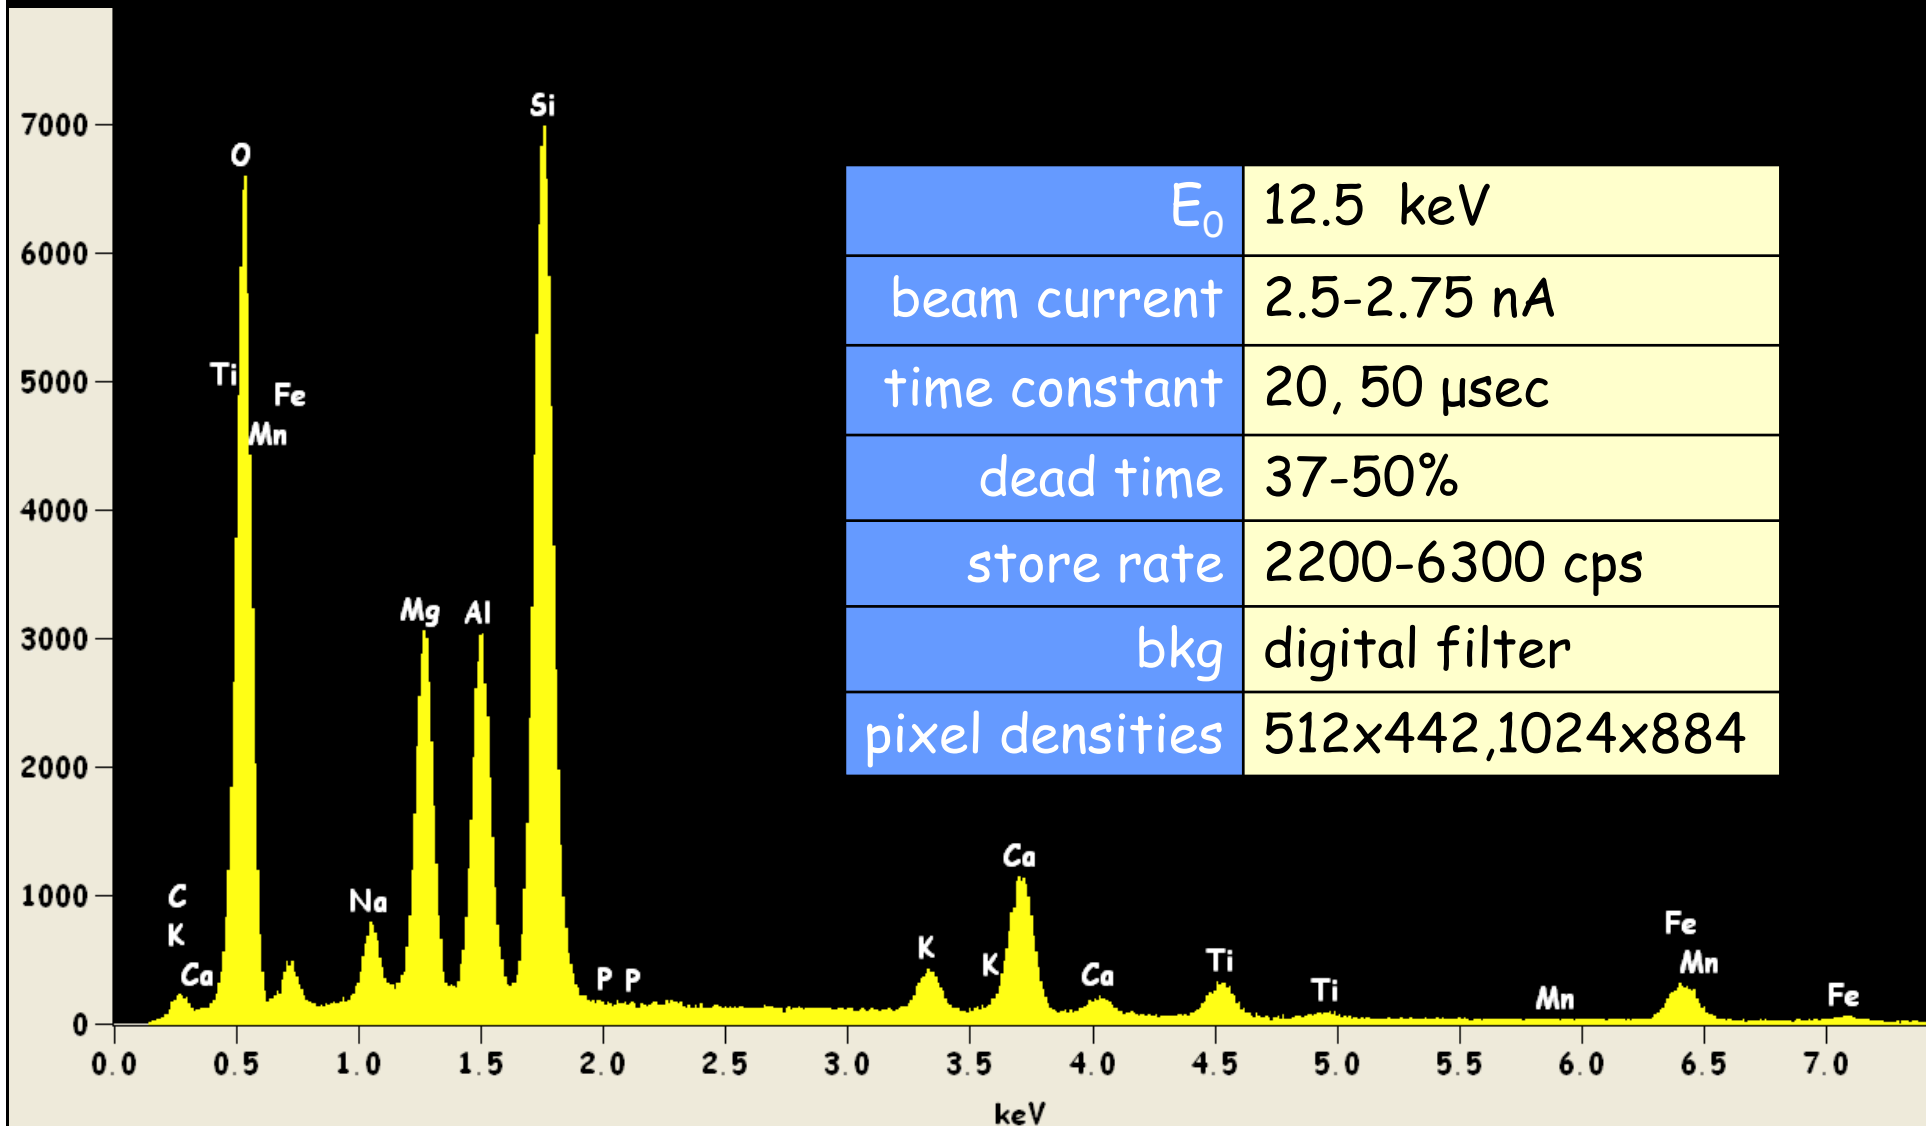

More Phase Segmentation X Phase

- If overlap occurs then combine overlap into the first detected phase for that area
- From each binary mask extract a spectrum from the datacube

Now you have a image (showing the location) and spectrum (giving the composition) pair for each chemical compound, or phase.

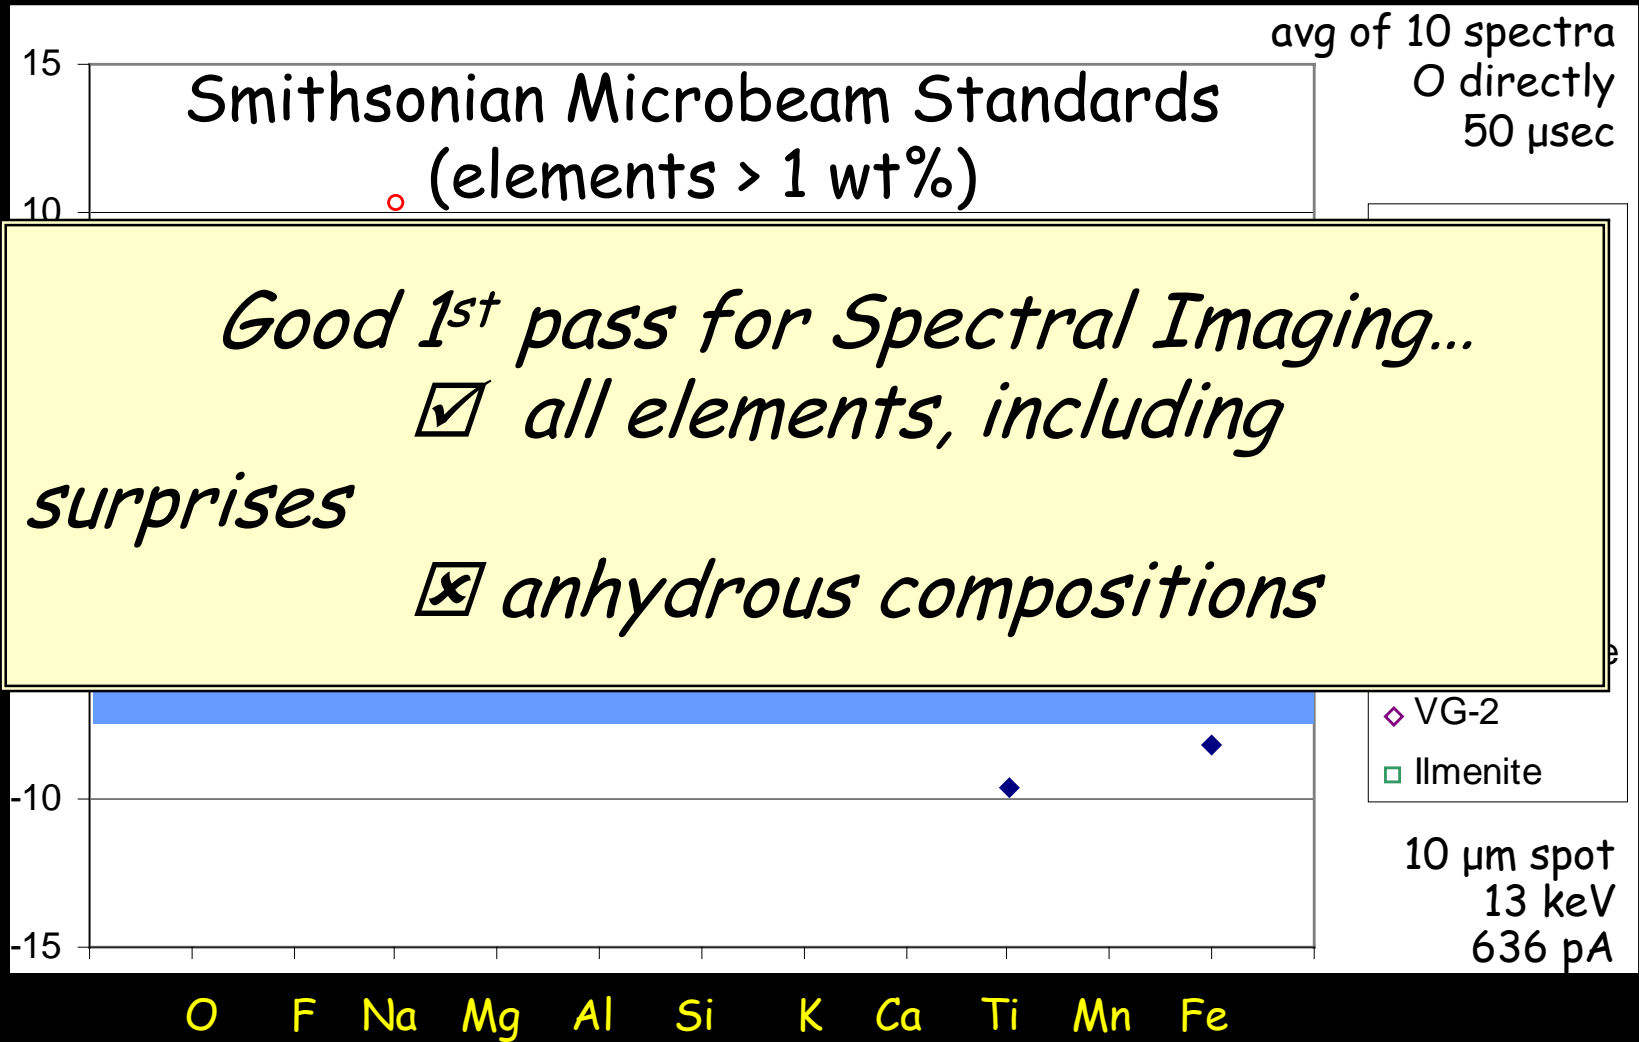

- Compare phase spectra to a library of stored phases using conventional least squares fit and give it a name
Note: Smithsonian mineral library will be available soon-

Quantification: Instrumental Conditions

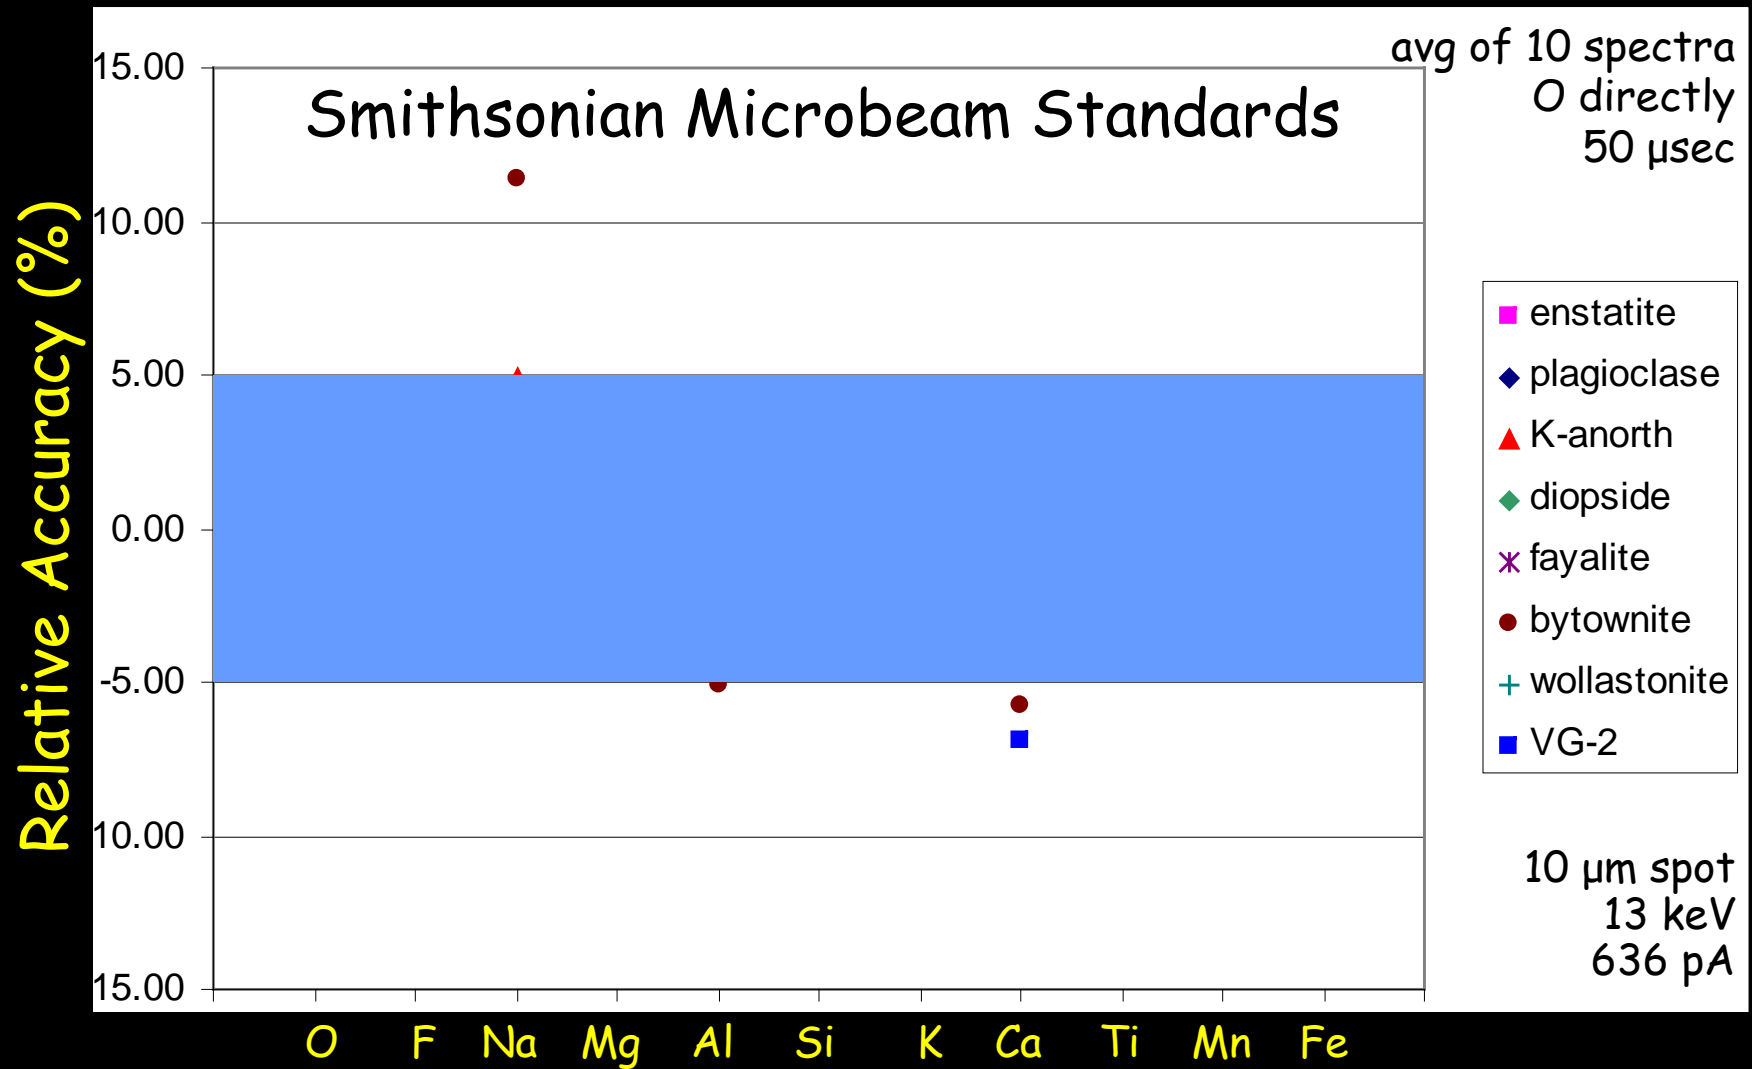

Quantification: "Standardless" EDS: *Useful or Worthless?*

Relative Accuracy (%)

Quantification: Standards-based EDS: *K-hornblende as primary std*

Parícutin Volcano

Mineralogical-Geological Glossary

Mineral name	End-member formulae
plagioclase	$\text{NaAlSi}_3\text{O}_8 - \text{CaAl}_2\text{Si}_2\text{O}_8$
olivine	$\text{Mg}_2\text{SiO}_4 - \text{Fe}_2\text{SiO}_4$
orthopyroxene	$\text{MgSiO}_3 - \text{FeSiO}_3$

term	definition
scoria	Rapidly cooled vesicular volcanic rock, darker than pumice.
ash	Particles of crystals and glass ejected into the atmosphere < 2 mm in diameter.

The Extraordinary Story of Parícutin Volcano

- In Feb. 1943 the volcano was born in the presence of several Tarascan indians, erupted for 9 years
- RARE event!
- Lava flows covered 25 km² burying 2 villages, killing 4500 cattle, 550 horses, and forcing the evacuation of several thousand people.
- Smithsonian has a special connection to the eruption as William Foshag, curator of mineralogy was in Mexico studying ore deposits when the birth occurred and documented the first 2.5 years of the volcano's life
- Foshag was an avid photographer and took lots of 16 mm footage
