# Quantum Coherence

---

- Coherent superposition with well-defined relative phase between **probability amplitudes**

**Two-level system:**

$$|\psi\rangle = C_a |a\rangle + C_b |b\rangle$$

e.g. atoms, spins

**Quantum coherence can be induced and manipulated via optical processes.**

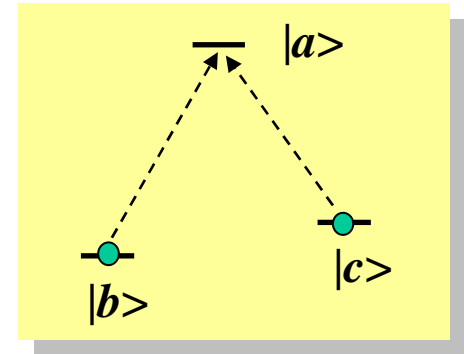

# Nonradiative Quantum Coherence

---

- **Nonradiative coherence:**

$$C_b |b\rangle + C_c |c\rangle$$

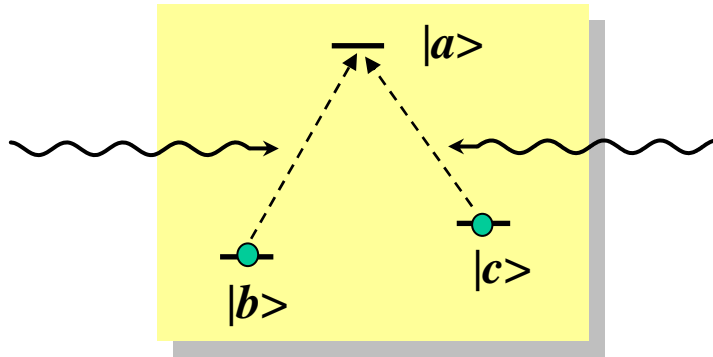

$|b\rangle$  and  $|c\rangle$  are not directly coupled by a dipole optical transition.

- **Quantum interference:**

Total optical transition rate depends on the **relative phase** of the probability amplitudes.

# Electromagnetically Induced Transparency (EIT)

$$|\psi\rangle = C_b |b\rangle + C_c |c\rangle$$

$$|C_a|^2 = |C_{b \rightarrow a} + C_{c \rightarrow a}|^2 = 0$$

Harris, *Physics Today* **50** (7), 36 (1997);  
Scully & Zubairy, *Quantum Optics*.

- **Population trapped state:** A special superposition state with

$$C_{b \rightarrow a} = -C_{c \rightarrow a}$$

- **EIT:** Vanishing optical absorption due to complete destructive quantum interference

# EIT: Quantum Interference Induced Transparency

- **Manybody interactions between excitons**

# Three Types of EIT Systems

---

**Demonstrated EIT using analogous systems in semiconductors:**

- a) **Exciton spin coherence** [Phys. Rev. Lett. **89**, 186401 (2002)]
- b) **Biexciton coherence** [Phys. Rev. Lett. **91**, 183602 (2003)]
- c) **Electron spin coherence** [Phys. Rev. B **70**, 153307 (2004); Phys. Rev. B **72**, 035343 (2005); Opt. Lett. **32**, 569 (2007).]

# Outline

---

- **Introduction**

- **EIT: Destructive interference via quantum coherence**
- **Why we are interested in EIT?**
- **Challenges for realizing EIT in semiconductors**

- **Experimental realization of EIT in semiconductors**

-  – **Exciton spin coherence**
- **Electron spin coherence**

- **Summary**

# Exciton Spin Coherence

- Exciton spin coherence: coherent superposition of spin-up and spin-down exciton states
  - The two transitions share no common state.
  - No exciton spin coherence can be induced in a non-interacting exciton system.

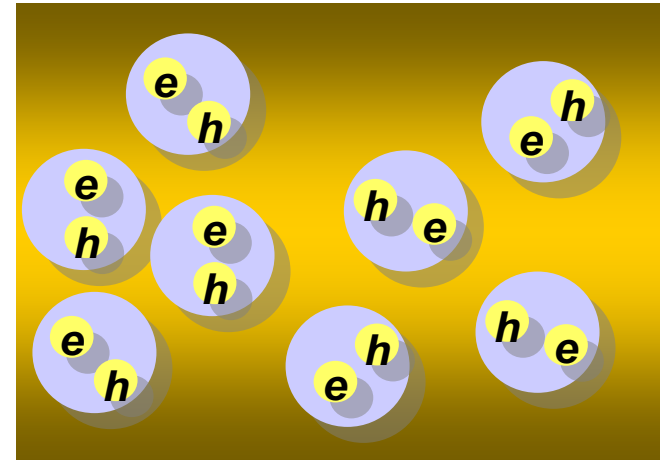

# Excitons: A Interacting Many-Particle System

- Exchange interaction:**

Exciton wave-functions start to overlap at relatively low densities.

$r_B \sim 10$  nm

- Coulomb correlation:**

For nearby excitons, charge fluctuations are strongly correlated.

**Attractive correlations can lead to the formation of exciton molecules or biexcitons.**

biexciton

# Exciton Spin Coherence via Biexcitons

- Coupling exciton spin states via biexcitonic transitions:

Taking advantage of manybody interactions between excitons to induce quantum coherence and realize EIT.

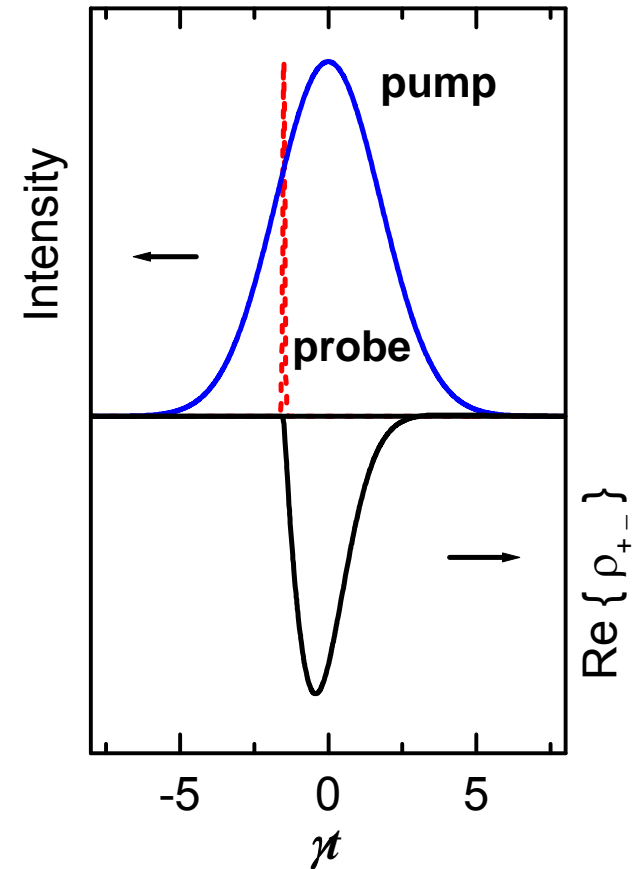

# EIT with Ultrafast Pulses

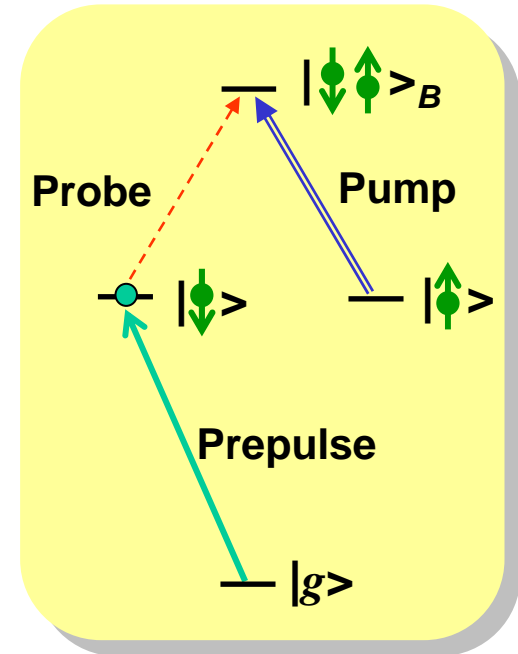

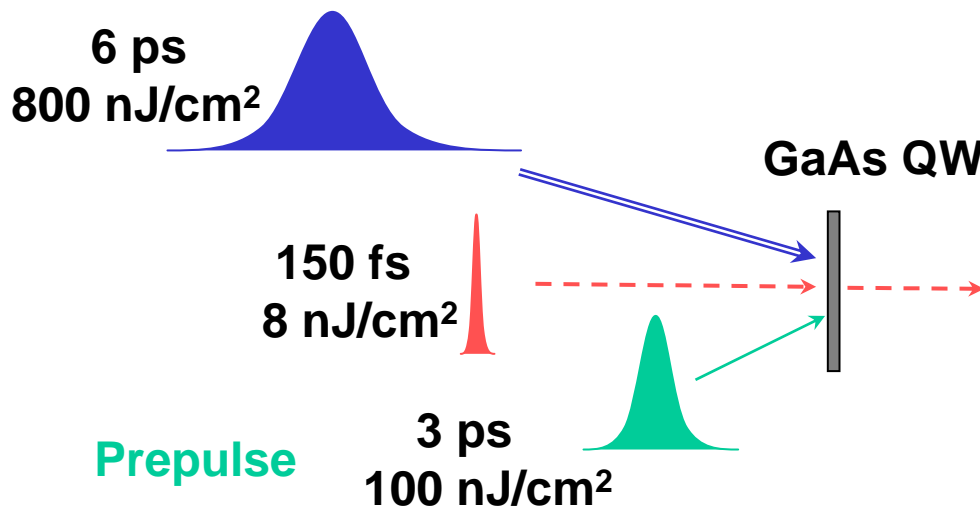

A **long** pump pulse and a **short** probe induce a spin coherence.

- Spin coherence

$\text{Re}(\rho_{+-}) < 0$ : Phased for **destructive** interference.

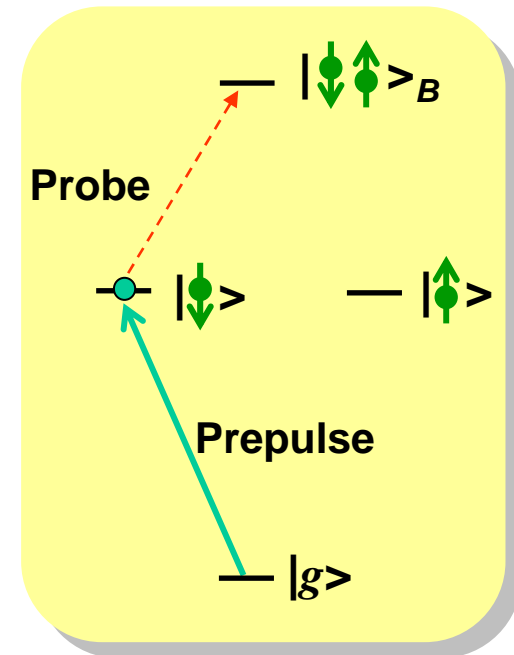

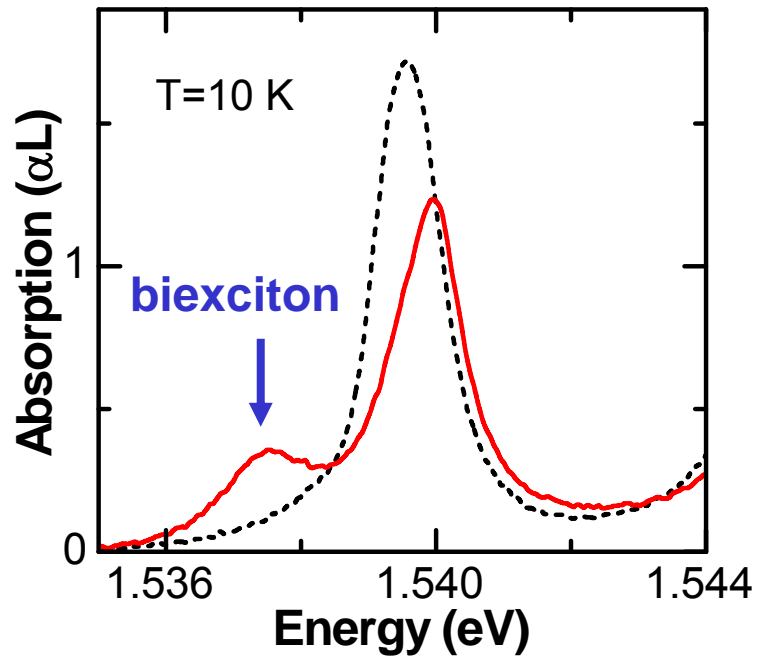

# Experimental Configuration

The prepulse pulse arrives 10 ps before the pump to inject spin-down excitons.

# Biexciton Resonance

10 nm GaAs/AlGaAs QW

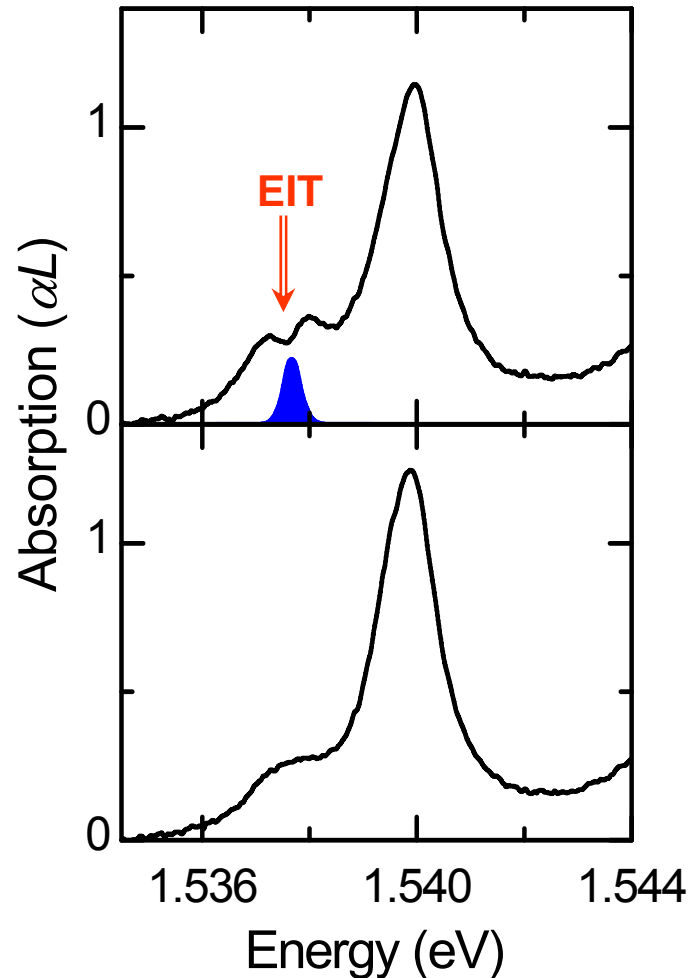

Dashed curve: Absorption spectrum without prepulse.  
Solid curve: Absorption spectrum with prepulse.

# EIT from Exciton Spin Coherence

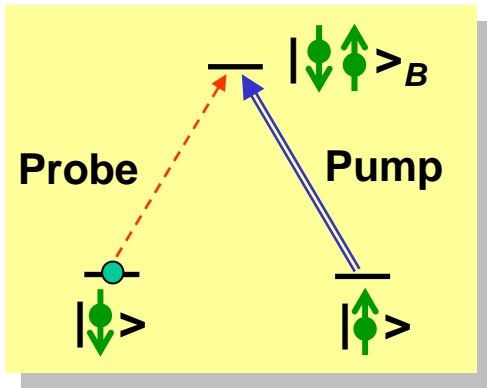

10 nm GaAs QW  
T=10 K

Phys. Rev. Lett. 89,  
186401 (2002).

# EIT from Spin Coherence

Theoretical calculation based on a 3-level model.

Dashed line: Absorption spectrum when the spin coherence is artificially turned off.

# Two-Exciton States

Axt and Stahl, Z. Phys. B **93**, 195 (1994).

Östreich *et al.*, Phys. Rev. Lett. **74**, 4698 (1995).

Kner *et al.*, Phys. Rev. Lett. **81**, 5386 (1998).

Sieh *et al.*, Phys. Rev. Lett. **82**, 3112 (1999).

**The two-exciton states play an essential role in coherent optical processes in semiconductors.**

Only 1s exciton states are included.

# Spin Coherence via Two-Exciton Scattering States

---

- Inducing spin coherence via two-exciton scattering states?

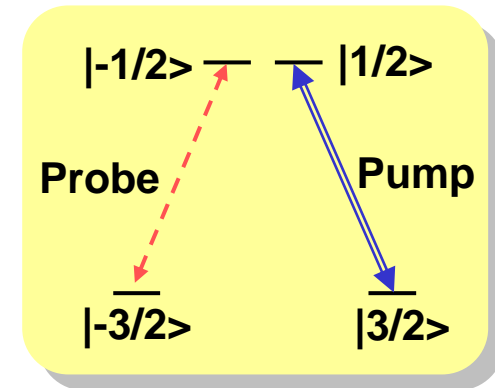

## Experiment:

The pump pulse excites excitons directly: **no prepulse is needed.**

EIT occurs at the energy of the exciton resonance.

# EIT via Exciton spin Coherence

Phys. Rev. Lett. 89, 186401 (2002).

10 nm GaAs QW

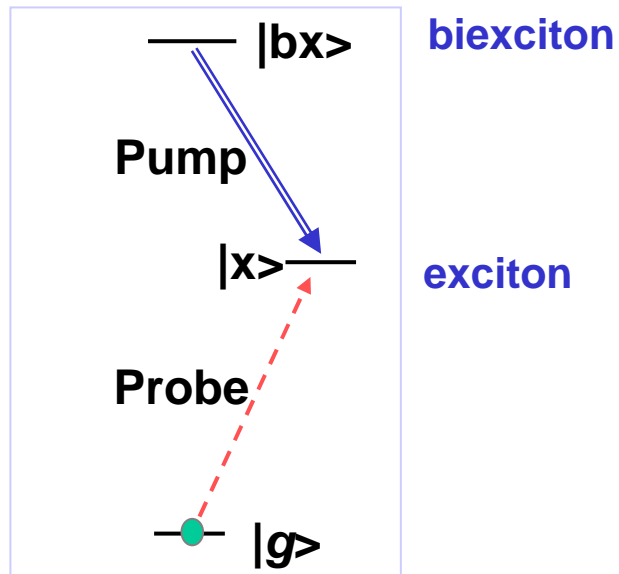

The pump and probe couple to transitions that share no common states.

**Exciton spin coherence induced via two-exciton continuum states can also lead to EIT.**

# EIT from Biexciton Coherence

Two pathways to drive the system to state  $|x\rangle$ :

$|g\rangle$  to  $|x\rangle$  &  $|bx\rangle$  to  $|x\rangle$

- **Biexciton coherence: Coherent superposition of  $|g\rangle$  and  $|x\rangle$ .**
- **The probe and pump couple to the exciton and biexciton transitions, respectively.**
- **The EIT dip occurs at the exciton absorption resonance.**

# EIT from Biexciton Coherence

- The pump is tuned slightly above the biexciton resonance.
- The absorption dip occurs at the exciton resonance.
- Delay dependence shows the coherent nature of the dip.

Phys. Rev. Lett. 91, 183602  
(2003).

# Outline

---

- **Introduction**

- **EIT: Destructive interference via quantum coherence**
- **Why we are interested in EIT?**
- **Challenges for realizing EIT in semiconductors**

- **Experimental realization of EIT in semiconductors**

- **Exciton spin coherence**
- **Electron spin coherence**

- **Future work**

# Electron Spin Coherence in Semiconductors

- Electron spin coherence is exceptionally robust.

can last as long as  $0.1 \mu\text{s}$  and remain robust at room temperature.

- Suitable three-level systems?

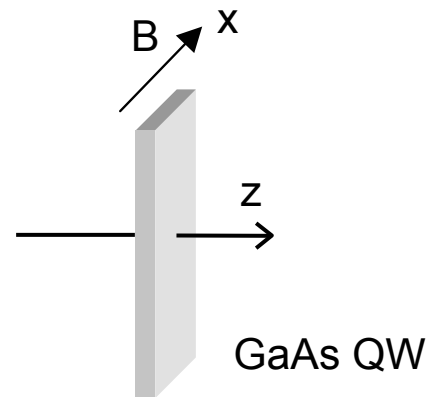

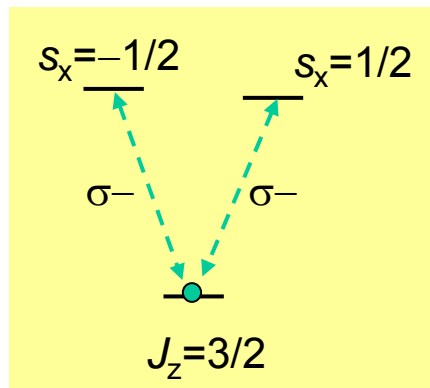

# Band Structure

- **The lowest energy interband transitions in a GaAs QW are characterized by two heavy-hole (HH) transitions.**
  - The two transitions share no common state.
  - No electron spin coherence can be induced.

# V-System in an External Magnetic Field

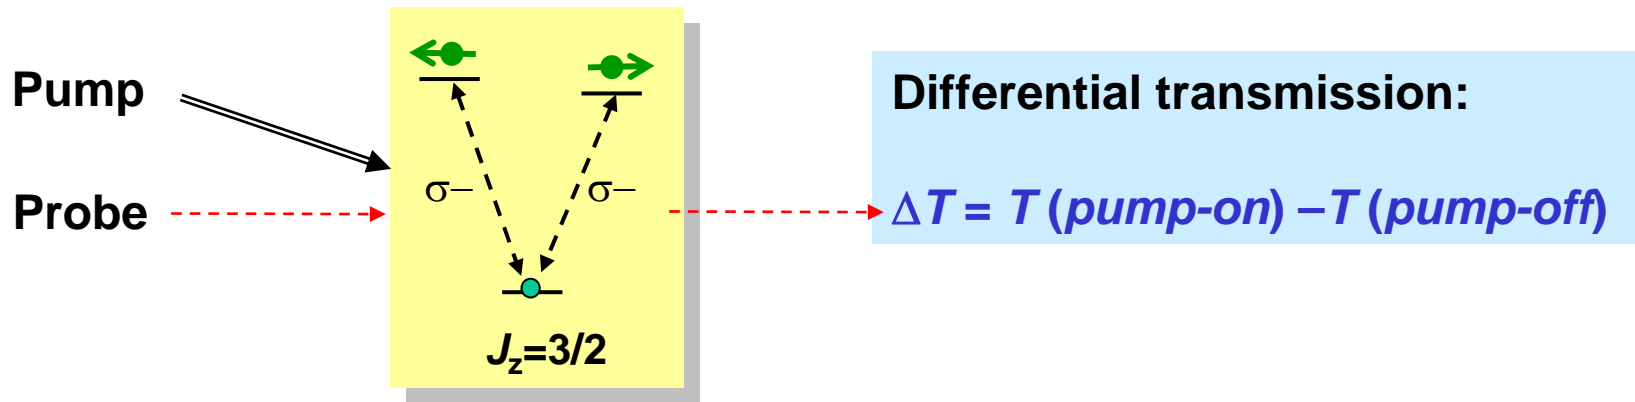

**Inducing spin coherence:** Coupling electron spin states to a common valence band state via dipole transitions.

**Voigt configuration**

- Electron spins are aligned with the external magnetic field.
- In a weak magnetic field,  $J_z$  remains approximately a good quantum number for the holes.

# CW EIT Experiments

- The pump and probe excite an electron spin coherence.
- Destructive interference induced by the spin coherence can lead to:
  - Induced resonance in transmission (dip in the absorption).

# Coherent Zeeman Resonance

$$\Delta T = T_{\text{Pump-on}} - T_{\text{pump-off}}$$

**The sharp Zeeman resonance arises from destructive interference induced by the electron spin coherence.**

# Polarization Dependence

Coherent Zeeman resonance in the cross-linear configuration can be viewed as EIT from the electron spin coherence.

# V-System without External Magnetic Fields

Using light hole transitions in a waveguide.

$$|j_z = 1/2\rangle = \frac{1}{\sqrt{3}} |Y_{11}\rangle |\downarrow\rangle + \sqrt{\frac{2}{3}} |Y_{10}\rangle |\uparrow\rangle$$

## Key features:

- Spin-orbit coupling mixes the spin-up and spin-down states for the light-hole (LH) band: **double-V system**.
- Inducing electron spin coherence in the absence of an external magnetic field.
- The waveguide geometry enables long interaction length.

# GaAs/AlGaAs QW Waveguide

**Sample:**  
Single 17.5 nm GaAs  
QW AlGaAs Cladding  
Length  $\sim 100\ \mu\text{m}$

**For TM polarization, HH exciton resonance is nearly negligible, as expected from optical selection rules.**

# EIT in a QW Waveguide

## Light-Hole exciton transition

# V-Type vs $\Lambda$ -type Three-Level Systems

---

- **V-System**

Spin decoherence is limited by radiative decay.

Degree of transparency is limited.

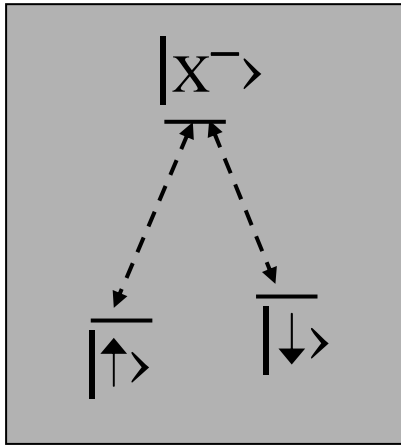

- **$\Lambda$ -System**

Spin states are the ground states.

Nearly complete transparency can be achieved.

# $\Lambda$ -type Three-Level System via Trions

- **Trion:**

An exciton bound to an electron (negatively charged exciton).

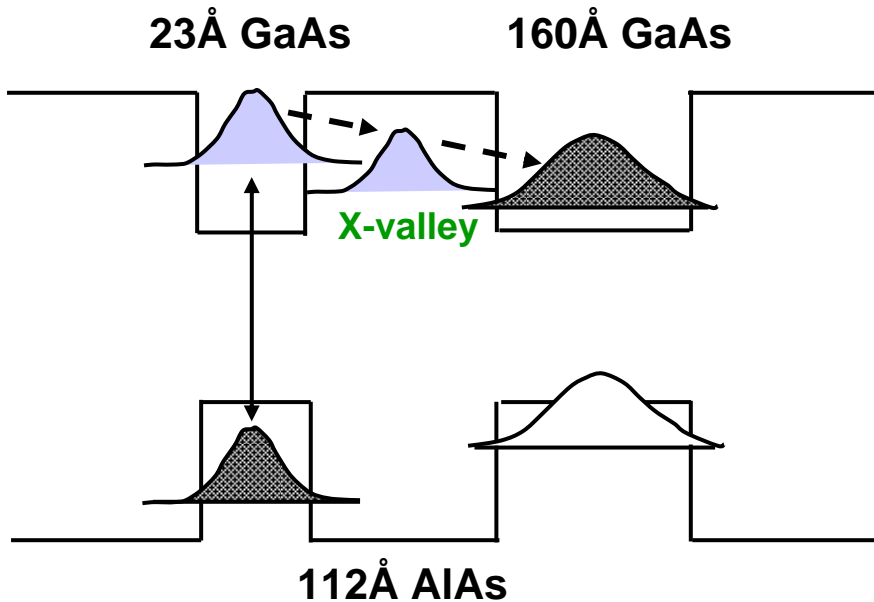

Involves two electrons and one hole.

Kheng *et al.*, PRL 71, 1752 (1993).

- The formation of the  $\Lambda$ -system requires an excess electron population in the conduction band.

# Mixed Type Quantum Well Structures

- **Mixed type QW:**

The bottom of the conduction band in the narrow QW is higher than the X-valley in the AlAs barrier.

Narrow well: type II

Wide well: type I

Galbraith et al., Phys. Rev. B 45, 013499 (1992).

- Electrons in narrow QW transfer via X-valley in the barrier to wide QW. Holes remain confined in the narrow QW.
- **Advantage: Using optical injection to control the electron density in the wide QW.**

# Formation of Trions in a Mixed-Type QW

- For black lines, the sample is excited by both the red and green laser beams.

- With increasing number of electrons in the wide well, more excitons are converted into trions.
- Trion binding energy: 1.6 meV

# $\Lambda$ -type Three-Level System via Trions

# Coherent Zeeman Resonance in the $\Lambda$ -System

- The width of the coherent Zeeman resonance corresponds to a spin decoherence time of 1 ns.

# Effects of Electron Injection

$$P^{NL} \propto \frac{1}{\gamma^2}$$

**The coherent response is quenched by the increased dipole decoherence induced by the carrier injection.**

- **Coherent Zeeman resonance amplitudes are suppressed with increased electron injection.**
- **The linewidth does not appreciably broaden .**

# Effects of Carrier-Carrier Interactions

**Red curve:** absorption spectrum obtained at an injection level of  $0.25 \text{ mW/cm}^2$

- Trion resonance present without injection due to residual doping.
- Trion absorption peak enhanced by the injection of electrons.
- Absorption resonance broadens dramatically due to efficient carrier-carrier carrier scattering.

**What is next?**

# Trions in II-VI Semiconductors

- CdTe/CdZnTe quantum well
- Modulation doping:  $2 \times 10^{10} / \text{cm}^2$

Kheng *et al.*, PRL 71, 1752 (1993).

- II-VI semiconductors feature greater binding energy.
- Pronounced and robust trion resonance in both absorption and emission spectra (the Y-resonance).

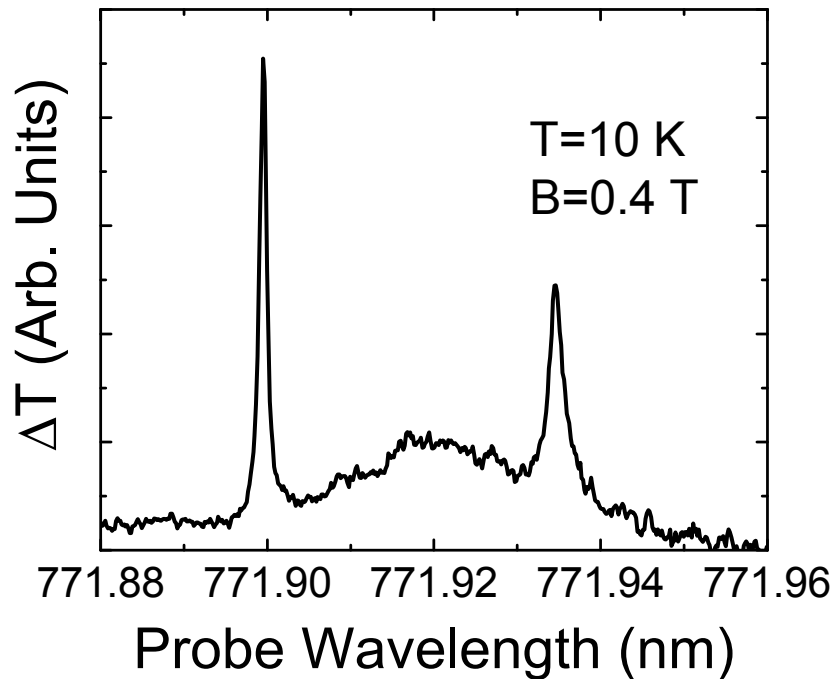

# Spin Precession from Trions in CdTe QW

---

- **Spin decoherence time  $\sim 1$  ns**
- **Modulation doping:  $2 \times 10^{10}/\text{cm}^2$**

# EIT from Trions in CdTe Quantum wells

- The pump is at the trion resonance ( $\lambda \sim 771.92$  nm).
- Pronounced coherent Zeeman resonance arising from destructive interference induced by the electron spin coherence.

## Future Work

---

- **Optimize the EIT process using trions and electron spin coherences.**
- **Coherent spin flipping via adiabatic passage.**
- **Incorporate EIT via trions in a waveguide geometry.**
- **Spin-phonon correlations.**
- **Generation of entangled photons.**

# Summary

---

- **Main Theme: EIT can be realized in semiconductors.**
  - **Demonstrated EIT with exciton spin coherence and biexciton coherence.**
  - **EIT can also be realized with robust electron spin coherence, opening possibilities for applications.**
  - **Manybody interactions between optical excitations modifies fundamentally coherent optical processes in semiconductors.**
