

(2). $H = \mathbb{k}[d]/(d^2)$, $K^*, L^* \in H\text{-gmod}$.

$$\begin{aligned} \text{Hom}_{H\text{-gmod}}(K^*, L^*) &= \frac{\{f: K^* \rightarrow L^* \mid d \circ f = (-1)^{|f|} f \circ d\}}{\{f = d \circ h = d \circ h - (-1)^{|h|} h \circ d\}} \\ &= \text{Hom}_{\text{Com}(\mathbb{k})}(K^*, L^*) . \end{aligned}$$

(3). $H = \mathbb{k}[\partial]/(\partial^p)$, $(\text{char}(\mathbb{k}) = p > 0)$, $K^*, L^* \in H\text{-gmod}$.

$$\text{Hom}_{H\text{-gmod}}(K^*, L^*) = \frac{\{f: K^* \rightarrow L^* \mid \partial \circ f = f \circ \partial\}}{\{f = \partial^p \circ h = \sum_{i=0}^{p-1} \partial^i \circ h \circ \partial^{p-1-i}\}} .$$

Def. $H = \mathbb{k}[\partial]/(\partial^p)$ ($\text{char}(\mathbb{k}) = p > 0$)

(1) The category of p -complexes $:= H\text{-gmod}$.

(2) The homotopy category of p -complexes $:= H\text{-gmod}$.

Why care?

Lemma (Bernstein-Khovanov) $H\text{-gmod}$ is \otimes -triangulated, and

$$H\text{-gmod} \xrightarrow{K_0} \mathcal{O}_p$$

$$\oplus \otimes \longmapsto + \times$$

$$\{\square\} \longmapsto -1 \underline{a}$$

Proof sketch. \otimes descends to $H\text{-gmod}$: $I \otimes M$ and $M \otimes I$ are injective if I is.

$$(1) \quad M \otimes (K \rightarrow I_k \rightarrow K[\square]) = M \otimes K \rightarrow M \otimes I_k \rightarrow M \otimes K[\square] \\ \implies (M \otimes K)[\square] \cong (M \otimes K)[\square].$$

$$(2) \quad M \otimes \left(\begin{array}{ccc} K & \xrightarrow{f} & L \\ \downarrow & \# & \downarrow \\ I_k & \rightarrow & C_f \\ \downarrow & & \downarrow \\ K[\square] & = & K[\square] \end{array} \right) \implies M \otimes K \xrightarrow{\text{Id}_f} M \otimes L \rightarrow M \otimes C_f \rightarrow M \otimes K[\square] \\ \text{remains a d.t.}$$

Grothendieck group $K_0(\mathcal{H}\text{-gmod})$ is thus a ring, with

$$[K] \cdot [L] := [K \otimes L]$$

$$[\underline{k}] = 1 \quad [k\{i\}] = q^i$$

$K_0(\mathcal{H}\text{-gmod})$: generated by $k\{i\}$, subject to the only relation

$$[H\{i\}] = q^i (1 + q^2 + \dots + q^{p-1}) = 0$$

$$\implies K_0(\mathcal{H}\text{-gmod}) \cong \frac{\mathbb{Z}[q, q^{-1}]}{(1 + \dots + q^{p-1})} = \mathbb{O}_p.$$

□

$H\text{-gmod} : \text{categorical } \mathcal{O}_p.$

Question: (1) How do we categorify modules over \mathcal{O}_p ?

(2). How do we categorify algebras over \mathcal{O}_p (e.g. $U_{\mathfrak{g}}(\mathfrak{g})$, $\mathfrak{g}^p=1$)?

(3). How do we categorify $U_{\mathfrak{g}}(\mathfrak{g})$ modules and their tensor products?

Categorification of $U_q(\mathfrak{sl}_2)$ at root of 1

Categorifying modules over \mathcal{O}_p

In usual homological algebra, modules over \mathbb{Z} arise as $K_0(A\text{-mod})$, $K_0(\text{Sh}(X))$ etc. These categories $A\text{-mod}$ and $\text{Sh}(X)$ can be described by differential graded algebras (DGA).

$$A = \bigoplus_{i \in \mathbb{Z}} A^i, \quad d_A : A^i \rightarrow A^{i+1} \quad \text{s.t.} \quad \forall a, b \in A$$

$$d_A^2(a) = 0,$$

$$d_A(ab) = d_A(a)b + (-1)^{|a|} a d_A(b).$$

Def. A p -DG algebra (A, ∂_A) is a graded algebra over a field of char $p > 0$, equipped with a degree-one endomorphism ∂_A , s.t. $\forall a, b \in A$,

$$\partial_A^p(a) = 0,$$

$$\partial_A(ab) = \partial_A(a)b + a\partial_A(b)$$

A p -DG module (M, ∂_M) over a p -DG algebra (A, ∂_A) is a graded A -module M with a degree-one endomorphism ∂_M , s.t. $\forall a \in A, m \in M$,

$$\partial_M^p(m) = 0,$$

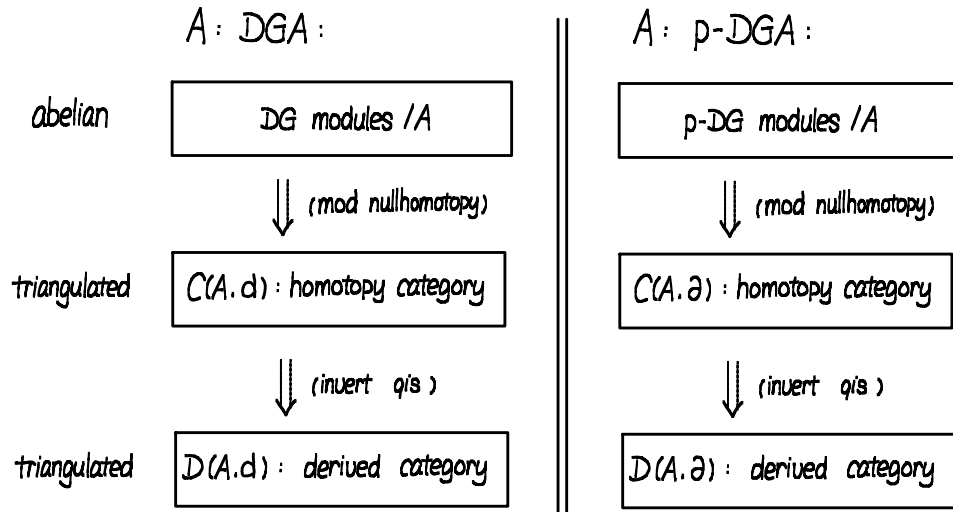

$$\partial_M(am) = \partial_A(a)m + a\partial_M(m).$$

Examples

- (1). $k[x]$: polynomial ring over k , $\text{char} k = p > 0$. Define a p -differential by setting $\partial(x) := x^2$ and extend it to $k[x]$ by the Leibniz rule. Then $(k[x], \partial)$ is a p -DGA.

- (2) Consider $A = M_n(k)$, and J a (direct sum of) Jordan matrix of size $(s) \leq p$. Define $\partial_J(X) := [J, X]$. Then (A, ∂_J) is a p -DGA.

- (3). $\text{Sym}_n := k[x_1, \dots, x_n]^{S_n}$, where $\partial(x_i) = x_i^2$, is a p -DGA.

Generalization: Hopfological Algebra (Khovanov, Q.)

Thm. (Khouanov-Q) The derived category $\mathcal{D}(A, \partial)$ of p -DG modules over A admits a categorical action by $H\text{-gmod}$:

$$\begin{array}{ccc}
 H\text{-gmod} \times \mathcal{D}^f(A) & \xrightarrow{\otimes} & \mathcal{D}^f(A) \\
 \Downarrow & & \Downarrow \\
 \mathbb{O}_p \times K_0(A, \partial) & \xrightarrow{\times} & K_0(A, \partial)
 \end{array}$$

Why do we want to categorify $U_q(\mathfrak{sl}_2)$?

- Reshetikhin-Turaev - Witten :

$U_q(\mathfrak{sl}_2)$ is the quantized gauge group of 3d Chern-Simons theory.
($q^N = 1$)

- Crane-Frenkel :

Categorify 3d Chern-Simons to a 4d-TQFT.

$U_q(\mathfrak{sl}_2)$: quantized 2-gauge group ?

Quantum $u(2)$ at roots of unity

We are interested in the idempotent version of $u_q(u_2)$. It is generated over $\mathbb{Z}[q, q^{-1}]$ by pictures of the form

$$\begin{array}{c} \lambda+2 \quad \uparrow \quad \lambda \\ \hline E \end{array} \quad \begin{array}{c} \lambda-2 \quad \downarrow \quad \lambda \\ \hline F \end{array} \quad (\lambda \in \mathbb{Z})$$

with the algebra structure

$$\begin{array}{c} \uparrow \downarrow \uparrow \uparrow \downarrow \lambda \\ \hline \end{array} \cdot \begin{array}{c} \mu \downarrow \downarrow \uparrow^{\mu+2} \\ \hline \end{array} = \delta_{\lambda\mu} \begin{array}{c} \uparrow \downarrow \uparrow \uparrow \downarrow \downarrow \downarrow \uparrow^{\mu+2} \\ \hline \end{array} \quad (\text{etc})$$

Modulo relations (at a $2k$ -th root of unity, k odd)

$$\begin{array}{c} \uparrow \quad \downarrow \quad \lambda \\ \hline E \quad F \end{array} = \begin{array}{c} \downarrow \quad \uparrow \quad \lambda \\ \hline F \quad E \end{array} + [\lambda] \begin{array}{c} \lambda \\ \hline \end{array} \quad (\lambda \geq 0)$$

$$\begin{array}{c} \downarrow \quad \uparrow \quad \lambda \\ \hline F \quad E \end{array} = \begin{array}{c} \uparrow \quad \downarrow \quad \lambda \\ \hline E \quad F \end{array} + [-\lambda] \begin{array}{c} \lambda \\ \hline \end{array} \quad (\lambda \leq 0)$$

$$\underbrace{\begin{array}{c} \uparrow \quad \dots \quad \uparrow \quad \uparrow \quad \uparrow \quad \lambda \\ \hline \end{array}}_{k\text{-many}} = 0 = \underbrace{\begin{array}{c} \downarrow \quad \dots \quad \downarrow \quad \downarrow \quad \downarrow \quad \lambda \\ \hline \end{array}}_{k\text{-many}} \quad (\text{Nilpotency relation})$$

Categorification of $U_q(\mathfrak{sl}_2)$ (à la Khovanov-Lauda-Rouquier)

To categorify quantum groups, we want introduce an extra dimension ("time") to study "evolution" of quantum states:

$$\begin{array}{c} \uparrow \quad \downarrow \quad \lambda \\ \text{---} \\ \text{E} \quad \text{F} \end{array} = \begin{array}{c} \downarrow \quad \uparrow \quad \lambda \\ \text{---} \\ \text{F} \quad \text{E} \end{array} + [\lambda] \text{---} \lambda$$

$$\Downarrow$$

$$\begin{array}{c} \text{F} \quad \text{E} \quad \lambda \\ \downarrow \quad \uparrow \quad \text{---} \quad \lambda \\ \oplus \quad [\lambda] \text{---} \lambda \\ \boxed{\text{S} \quad ???} \\ \uparrow \quad \downarrow \quad \lambda \\ \text{E} \quad \text{F} \end{array}$$

The rough idea:

- 1-D pictures (horizontal slices) = (isomorphism classes of) projective modules $E^i(\mathcal{F})$...
- 2-D pictures (vertical) = maps (evolution) between modules corresponding to 1-D slices
- Sum of 1-D pictures = symbol of direct sum of modules
- Equality of 1-D pictures = isomorphisms of modules.

Below we present Lauda's diagrammatic calculus for $U_q(\mathfrak{sl}_2)$

- Maps just among E's (or F's).

subject to nilHecke relations:

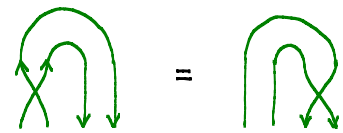

$$\begin{array}{c} \bullet \\ \nearrow \\ \searrow \\ \bullet \end{array} - \begin{array}{c} \nearrow \\ \bullet \\ \searrow \\ \bullet \end{array} = \uparrow \quad \uparrow = \begin{array}{c} \nearrow \\ \bullet \\ \searrow \\ \bullet \end{array} - \begin{array}{c} \bullet \\ \nearrow \\ \searrow \\ \bullet \end{array}$$

$$\begin{array}{c} \nearrow \\ \searrow \\ \nearrow \\ \searrow \end{array} = 0 \quad \begin{array}{c} \nearrow \nearrow \\ \searrow \searrow \end{array} = \begin{array}{c} \nearrow \searrow \\ \searrow \nearrow \end{array}$$

- To categorically connect E and F 's, Lauda introduces cups and caps

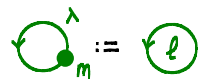

Together with the nilHecke algebra generators, cups and caps satisfy certain relations

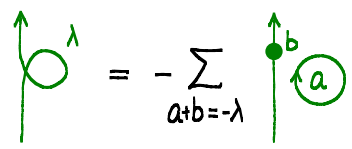

(i) Biadjointness E.g. 

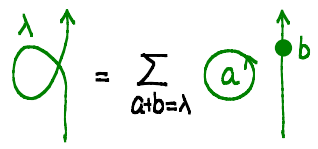

(ii) Bubble positivity : degrees of

 $k = m + 1 - \lambda \geq 0$

 must be ≥ 0 .
 $\ell = m + 1 + \lambda \geq 0$

(iii) Reduction to bubbles

(v). Identity decomposition

$$\lambda \begin{array}{|c|} \hline \uparrow \\ \hline \end{array} \begin{array}{|c|} \hline \downarrow \\ \hline \end{array} = - \begin{array}{|c|} \hline \text{X} \\ \hline \end{array} + \sum_{a+b+c=\lambda-1} \lambda \begin{array}{|c|} \hline \bullet a \\ \hline \text{b} \\ \hline \bullet c \\ \hline \end{array}$$

$$\lambda \begin{array}{|c|} \hline \downarrow \\ \hline \end{array} \begin{array}{|c|} \hline \uparrow \\ \hline \end{array} = - \begin{array}{|c|} \hline \text{X} \\ \hline \end{array} + \sum_{a+b+c=\lambda-1} \lambda \begin{array}{|c|} \hline \bullet a \\ \hline \text{b} \\ \hline \bullet c \\ \hline \end{array}$$

Thm. (Lauda) This graphical calculus, denoted \mathcal{U} , is non-degenerate and categorifies $U_{\mathbb{Z}}(\mathfrak{sl}_2)$ at a generic q -value.

Rmk: Lauda's calculus is a 2-dim'l idempotented algebra, i.e. it has two compatible multiplication structures (vertical and horizontal). Such idempotented algebras are also known as a "2-category".

To illustrate the proof of Lauda's thm, let us consider how

$$\begin{array}{c} \uparrow \\ \text{---} \\ \downarrow \\ E \quad F \end{array} \overset{\lambda}{\quad} \text{"evolves" into} \begin{array}{c} \downarrow \quad \uparrow \\ \text{---} \\ \downarrow \quad \uparrow \\ F \quad E \end{array} \oplus \text{---} \overset{\lambda}{\quad} \oplus [\lambda]$$

According to the previous philosophy:

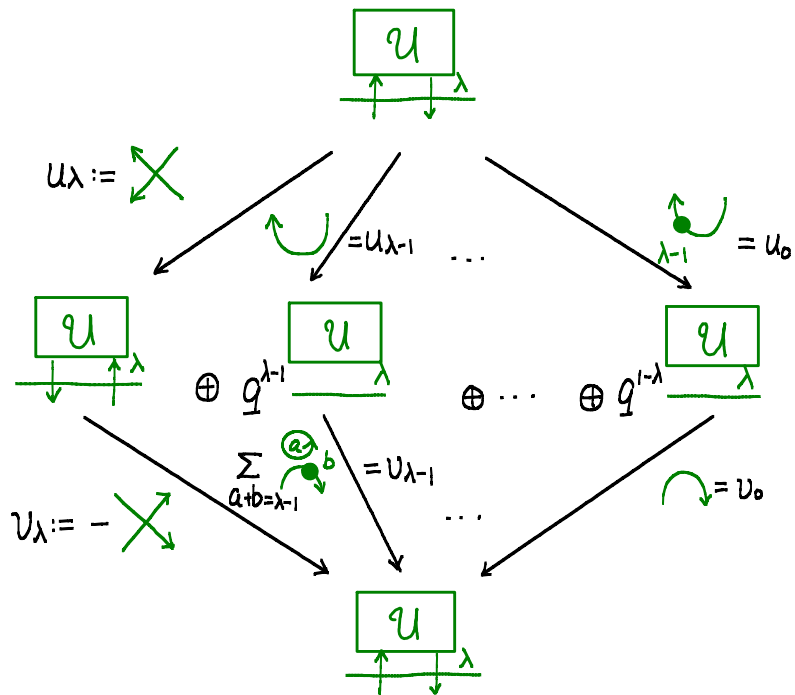

$$\begin{array}{c} \uparrow \\ \text{---} \\ \downarrow \\ E \quad F \end{array} \implies \begin{array}{c} \boxed{\mathcal{U}} \\ \uparrow \quad \downarrow \\ \text{---} \\ E \quad F \end{array} \overset{\lambda}{\quad}$$

Maps between $\begin{array}{c} \uparrow \\ \text{---} \\ \downarrow \\ E \quad F \end{array} \overset{\lambda}{\quad}$ & $\begin{array}{c} \downarrow \\ \text{---} \\ \downarrow \\ F \quad E \end{array} \overset{\lambda}{\quad}$ \implies $\begin{array}{c} \boxed{\mathcal{U}} \\ \uparrow \quad \downarrow \\ \text{---} \\ \boxed{???} \\ \downarrow \quad \uparrow \\ F \quad E \end{array} \overset{\lambda}{\quad}$

In general, to show that there is an isomorphism of A -modules $M \cong K \oplus L \iff \exists A$ -module maps

s.t. $Id_M = v_1 u_1 + v_2 u_2$, $u_1 v_1 = Id_K$, $u_2 v_2 = Id_L$, $u_1 v_2 = u_2 v_1 = 0$
 $\implies v_1 u_1, v_2 u_2$ are orthogonal idempotents in $End_A(M)$.

These elements $\{u_\lambda\}, \{v_\lambda\}$ satisfy

$$\begin{cases} v_i u_i = Id_i \\ v_i u_j = 0 \quad (i \neq j) \\ \sum u_i v_i = Id_{\mathcal{EF}1_\lambda} \end{cases}$$

which follows from the identity decomposition relation.

Consequently $\{u_i v_i \mid i=0, \dots, \lambda\}$ form an orthogonal set of idempotents in $\text{End}_{\mathcal{U}}(\mathcal{EF}1_\lambda)$

(Factorization of idempotents)

Enhancing \mathcal{U} with a p -differential

Def. Let (\mathcal{U}, ∂) be Lauda's 2-dimensional algebra equipped with the differential ∂ -action on generators

$$\partial(\uparrow \bullet) = \uparrow \bullet \quad \partial(\begin{array}{c} \nearrow \\ \searrow \end{array}) = \uparrow \uparrow - 2 \begin{array}{c} \nearrow \bullet \\ \searrow \end{array}$$

$$\partial(\downarrow \bullet) = \downarrow \bullet \quad \partial(\begin{array}{c} \searrow \\ \nearrow \end{array}) = -\downarrow \downarrow - 2 \begin{array}{c} \searrow \bullet \\ \nearrow \end{array}$$

$$\partial(\begin{array}{c} \curvearrowright \\ \lambda \end{array}) = \begin{array}{c} \curvearrowright \bullet \\ \lambda \end{array} - \begin{array}{c} \curvearrowright \\ \lambda \end{array} \textcircled{1} \quad \partial(\begin{array}{c} \curvearrowleft \\ \lambda \end{array}) = (1-\lambda) \begin{array}{c} \curvearrowleft \bullet \\ \lambda \end{array}$$

$$\partial(\begin{array}{c} \curvearrowleft \\ \lambda \end{array}) = \begin{array}{c} \curvearrowleft \bullet \\ \lambda \end{array} + \begin{array}{c} \curvearrowleft \\ \lambda \end{array} \textcircled{1} \quad \partial(\begin{array}{c} \curvearrowright \\ \lambda \end{array}) = (\lambda+1) \begin{array}{c} \curvearrowright \bullet \\ \lambda \end{array}$$

Lemma. The above ∂ preserves all relations of \mathcal{U} , and it is p -nilpotent over a field of characteristic $p > 0$.

Proof is a good exercise practicing with relations.

Thm. (Khovanov-Q., Elias-Q.) The derived module category $\mathcal{D}^b(\mathcal{U}, \partial)$ categorifies $u_q(\mathfrak{sl}_2)$ at a p -th primitive root of 1:

$$K_0(\mathcal{U}, \partial) \cong u_q(\mathfrak{sl}_2)$$

Decomposition v.s. filtration

In the realm of triangulated categories, direct sum decompositions are very rare.

Instead, a short exact sequence of p -DG \mathcal{U} -modules gives rise to a distinguished triangle in $D(\mathcal{U}, \partial)$.

$$\begin{array}{ccccccc} 0 & \longrightarrow & K & \xrightarrow{v} & M & \xrightarrow{u} & L \longrightarrow 0 & \text{in } (\mathcal{U}, \partial)\text{-mod} \\ & & & & \Downarrow & & & \\ & & K & \xrightarrow{v} & M & \xrightarrow{u} & L \xrightarrow{\partial} A[\square] & \text{in } D(\mathcal{U}, \partial) \\ & & & & \Downarrow & & & \\ & & [M] & = & [K] & + & [L] & \text{in } K_0(\mathcal{U}, \partial) \end{array}$$

More generally, a filtered p -DG module (M, F^\bullet) presents M as a convolution (Postnikov tower) of $\text{gr}F^\bullet$.

$$\begin{array}{ccccccc}
 0 & \longrightarrow & F^1 & \hookrightarrow & F^2 & \hookrightarrow & \dots & \hookrightarrow & F^n = M \\
 & & \swarrow & & \swarrow & & \swarrow & & \swarrow \\
 & & & & F^2/F^1 & & \dots & & F^n/F^{n-1} \\
 & & & & \swarrow & & \swarrow & & \swarrow \\
 & & & & & & F^3/F^2 & &
 \end{array}$$

$$\Rightarrow [M] = \sum_i [F^i/F^{i-1}] \text{ in } K_0(\mathcal{U}, \partial).$$

Prop. Let $\{(u_i, v_i) \mid i \in I\}$ be factorization of idempotents in a p -DG algebra A . If there is a total ordering on I such that

$$\begin{cases} v_i \partial(u_i) = 0 \\ u_i \partial(v_i) \equiv 0 \pmod{\sum_{j < i} A u_j v_j} \end{cases}$$

Then if $\varepsilon = \sum_{i \in I} u_i v_i$, then the p -DG module $A\varepsilon$ admits a filtration F^\bullet whose subquotients are isomorphic to $A v_i u_i$'s

Cor. In the situation of the Prop. $[A\varepsilon] = \sum_{i \in I} [A v_i u_i]$.

Proof of Prop.

Define $F^i := \sum_{j < i} A u_j v_j$. Then $F^i / F^{i-1} \cong A u_i v_i$.

(1). Inductively, F^i is ∂ -closed, i.e. $\partial(u_i v_i) \in F^i$:

$$\partial(u_i v_i) = \partial(u_i) v_i + u_i \partial(v_i) = \partial(u_i) v_i u_i v_i + u_i \partial(v_i) \in A u_i v_i + F^{i-1} = F^i.$$

(2). $A v_i u_i$ is ∂ -closed:

Clear, since $v_i u_i = \text{Id}_i$

(3). There is a p-DG module isomorphism:

$$(A u_i v_i \cong) F^i / F^{i-1} \begin{array}{c} \xrightarrow{\cdot u_i} \\ \xleftarrow{\cdot v_i} \end{array} A u_i u_i$$

(ex).

□

Cor. Under the differential defined earlier on \mathcal{U} , there is a filtration on $E\mathcal{F}1_\lambda$
