Abstract: The enzymatic conversion of carbonyl sulfide (COS) to hydrogen sulfide (H\(_2\)S) by carbonic anhydrase has been used to develop self-immolating thiocarbamates as COS-based H\(_2\)S donors to further elucidate the impact of reactive sulfur species in biology. The high modularity of this approach has provided a library of COS-based H\(_2\)S donors that can be activated by specific stimuli. A common limitation, however, is that many such donors result in the formation of an electrophilic quinone methide byproduct during donor activation. As a mild alternative, we demonstrate here that dithiasuccinoyl groups can function as COS/H\(_2\)S donor motifs, and that these groups release two equivalents of COS/H\(_2\)S and uncage an amine payload under physiologically relevant conditions. Additionally, we demonstrate that COS/H\(_2\)S release from this donor motif can be altered by electronic modulation and alkyl substitution. This insights are further supported by DFT investigations, which reveal that aryl and alkyl thiocarbamates release COS with significantly different activation energies.

Introduction

Despite being a malodorous gas,\(^{[1]}\) hydrogen sulfide (H\(_2\)S) is an important biological signaling molecule often referred to as a gasotransmitter alongside carbon monoxide and nitric oxide.\(^{[2]}\) H\(_2\)S-mediated signaling is important in several physiological processes including vasodilation,\(^{[3]}\) neurotransmission,\(^{[4]}\) and inflammation.\(^{[5]}\) These findings have led researchers to propose the use of H\(_2\)S as a potential therapeutic agent for a variety of conditions and pathologies.\(^{[6]}\) Toward this goal, researchers have relied heavily on the use of NaSH and Na\(_2\)S as sources of H\(_2\)S due to ease of handling and commercial availability; however, H\(_2\)S release from these salts is considerably different relative to enzymatic H\(_2\)S generation.\(^{[7]}\) To better mimic endogenous H\(_2\)S production, methods of generating H\(_2\)S at controlled rates under physiologically-relevant conditions are needed;\(^{[8]}\) and the development of small molecule “H\(_2\)S donors” is an active research area aimed at addressing this need.\(^{[9]}\) Such compounds typically generate H\(_2\)S by passive hydrolysis\(^{[10]}\) or activation in the presence of specific stimuli including light,\(^{[11]}\) biological thiols,\(^{[12]}\) and cellular enzymes including esterases.\(^{[13]}\)

Recently, an alternative approach to H\(_2\)S generation has utilized the hydrolysis of carbonyl sulfide (COS) by carbonic anhydrase (CA), a ubiquitous metalloenzyme.\(^{[14]}\) Existing in Nature as the most abundant sulfur-containing gas in the atmosphere,\(^{[15]}\) COS is rapidly converted to H\(_2\)S and carbon dioxide (CO\(_2\)) in the presence of bovine carbonic anhydrase II (k\(_{\text{cat}}/K_{\text{M}} = 2.2 \times 10^{8} \text{ M}^{-1} \text{ s}^{-1}\)).\(^{[16]}\) In our initial approach, we were inspired by self-immolative carbamates, which release CO\(_2\) as a byproduct upon activation,\(^{[17]}\) and developed analogous self-immolative thiocarbamates that function as tunable COS-based H\(_2\)S donors (Figure 1a).\(^{[18]}\)

The high modularity of self-immolative COS-releasing motifs has enabled the rapid expansion of this approach by our group\(^{[19]}\) as well as others to prepare COS-based H\(_2\)S donors activated by various stimuli including acidic pH,\(^{[20]}\) esterases,\(^{[21]}\) reactive oxygen species,\(^{[22]}\) and cysteine.\(^{[23]}\) This approach has also been extended to provide oligomeric COS-based H\(_2\)S donors.\(^{[23]}\) A critical, yet often overlooked component of this approach is the formation of a quinone methide byproduct, which is a potent electrophile and known Michael acceptor in biological systems.\(^{[24]}\) Although we have not observed cytotoxicity from this byproduct in our studies, chronic exposure from therapeutic administration of these compounds may induce electrophilic stress leading to long-term cytotoxicity.\(^{[25]}\) As an alternative approach, Matson and co-workers have reported both small molecule and polymeric N-thiocarboxylyhydrides (NTAs) as COS/H\(_2\)S donors, which only result in small peptide byproducts.\(^{[26]}\) These donor compounds, however, exhibit a relatively low H\(_2\)S-releasing efficiencies. To further develop COS-based H\(_2\)S donors as both research tools and potential pharmacological agents, alternative donor motifs are needed that lack electrophilic byproducts, maximize COS/H\(_2\)S release, and allow for simple tuning of release rates.
To address these needs, we focused on the reactivity of the dithiasuccinocarbamoyl (DTS) group, which has been used previously as a protecting group for amines in peptide synthesis. The DTS group is cleaved by thiols, which results in reduction to a symmetric disulfide, two equivalents of COS, and an amine (Figure 1b). We note that previous studies on thiol-mediated reduction of DTS groups examined this reactivity in organic solvents using β-mercaptoethanol as the reductant and quantified reaction kinetics through the use of an amino acid analyzer without direct observation of COS. We envisioned that this reactivity could be harnessed to prepare a library of COS-based H$_2$S donors that do not release electrophilic byproducts, but that readily release COS/H$_2$S under physiologically relevant conditions in the presence of CA. Herein, we demonstrate that DTS-caged amines function as versatile COS/H$_2$S donors activated by biological nucleophiles, including cysteine and reduced glutathione (GSH). Additionally, we use a combination of experimental and computational investigations to demonstrate that the rate of COS/H$_2$S release can be readily tuned by electronic modulation and subsequent stabilization of the COS-releasing thiocarbamate intermediate.

**Results and Discussion**

To prepare a small library of COS-based H$_2$S donors with tunable release rates, we treated alkyl and aryl isothiocyanates with N,N-dimethylthanolamine in the presence of sodium hydride to generate the desired thiocarbamate intermediate. Subsequent treatment with chlorocarbonylsulfenyl chloride afforded the desired DTS-caged compounds (Scheme 1). The amines chosen for this library included alkyl amines with different electron donating/withdrawing properties, as well as aryl amines with increasing steric bulk.

To assess the viability of these compounds as COS/H$_2$S donors, we examined the release of H$_2$S from PhDTS (25 μM) in the presence of biologically-relevant nucleophiles (500 μM, 20 equiv) and CA (25 μM) using the methylene blue assay to measure H$_2$S generation (Figure 2). Our expectation was that this donor functional group would be activated broadly by different nucleophiles rather than one specific biological nucleophile, thus broadening the scope of potential activation pathways.

In the absence of CA, we did not observe hydrolysis-mediated H$_2$S release from PhDTS. The addition of cysteine to PhDTS in the absence of CA resulted in slow, yet gradual H$_2$S release. We attribute this observation to the hydrolysis of COS at physiological pH, which has been reported previously to be slow. Treatment of PhDTS with cysteine in the presence of CA resulted in significant H$_2$S generation. Using a calibration curve generated with known concentrations of NaSH, we measured 40 μM H$_2$S generation from 25 μM PhDTS in the presence of 500 μM cysteine, which corresponds to an H$_2$S releasing efficiency of 80% (Figure S45). This observation not only highlights the high efficiency of H$_2$S release from DTS-caged compounds, but also supports that two equivalents of COS are released per DTS group.

In addition to COS/H$_2$S release, we also observed the formation of aniline following treatment of PhDTS with cysteine by HPLC, which further supports the proposed releasing mechanism (Figure S48). Protection of the amine and/or carboxylate groups on cysteine did not significantly impact the rate or quantity of COS/H$_2$S release from PhDTS, which supports a thiol-mediated releasing pathway. Interestingly, the use of S-methyl cysteine resulted in slow, yet considerable H$_2$S release suggesting a less favorable, thiol-independent reaction pathway. In previous studies, the direct reaction of amines at the carbonyl position of DTS groups has been observed and proposed to result in the generation of COS and sulfane sulfur. We observed a similar rate of H$_2$S release in the presence of

**Scheme 1. Synthesis of DTS-based COS/H$_2$S donors.**

![Scheme 1](image-url)
lysine, which further supports a minor, amine-mediated mechanism of H$_2$S release. We note an induction phase in the rate of amine activation and find that this reaction is slower relative to the thiol-mediated reduction of DTS groups (Figure S49). Together with the decreased nucleophilicity of amines due to protonation at physiological pH and lower biological concentrations relative to thiols, we expect this mechanism of activation to be negligible in a biological context. In the presence of homocysteine and GSH, we observed lower quantities of COS/H$_2$S released, which we attribute to the lower nucleophilicity of these thiols as a function of thiolate/thiol speciation at physiological pH.[31] We failed to observe COS/H$_2$S release in the presence of serine, which implies that alcohol-mediated mechanisms are not a significant activation pathway.

In the presence of CA, but absence of any added nucleophiles, we did observe slight H$_2$S production. We hypothesized that this release could be due to coordination of PhDTS to the Zn$^{2+}$ center in CA, which would facilitate hydrolysis by carbonyl activation. To probe this reactivity, we pre-incubated CA with the CA inhibitor acetazolamide (5 $\mu$m) and measured H$_2$S release from PhDTS (Figure S46). Under these conditions, we failed to observe H$_2$S generation, which supports the hypothesis of a minor CA/Zn$^{2+}$-mediated hydrolysis mechanism. Alternatively, this could also be due to minor background DTS hydrolysis followed by COS conversion to H$_2$S by CA. Further experiments using a catalytic amount of Zn(OAc)$_2$ (5 $\mu$m) did not result in COS/H$_2$S release from PhDTS, which suggests the need for the protein microenvironment present in CA for activation of PhDTS (Figure S47).[32] Similar to the reactivity with amines, the rate of CA/Zn$^{2+}$-mediated hydrolysis is slower than the thiol-mediated reduction. Taken together, these results demonstrate the validity of PhDTS and related compounds to serve as COS/H$_2$S donors under physiologically relevant conditions in the presence of thiols and CA.

With a small library of DTS-based donors in hand, we next examined the effect of the amine payload on COS/H$_2$S release using each donor (25 $\mu$m) in the presence of cysteine (500 $\mu$m, 20 equiv) and CA (25 $\mu$g mL$^{-1}$) at physiological pH (Figure 3). We hypothesized that DTS-caging of functionalized anilines would allow COS/H$_2$S release rates to be tuned based on prior work aimed at solvent-dependent linear free energy relationship investigations into the phosphine-mediated sulfur extrusion from DTS.[33] Additionally, we expected that the caging of alkylamines would lead to stabilization of the COS-releasing thiocarbamic acid intermediate and subsequently decrease the rate of H$_2$S release relative to that observed for DTS-caged anilines. In the presence of cysteine and CA, we observed varying rates and quantities of H$_2$S release from the reported aryl-based DTS compounds with 3-MePhDTS and 4-tBuPhDTS displaying the fastest and slowest rates of H$_2$S release, respectively (Figure 3a). The releasing curves from the DTS-caged anilines did not fit cleanly to first-order exponential decay, which we attribute to competing COS-releasing and DTS consumption pathways, such as direct thiol activation versus CA-mediated activation. Additionally, previous work has reported the formation of isothiocyanates from sufficiently acidic thiocarbamates, which likely further complicates the rates of release from DTS-caged anilines containing electron-withdrawing groups.[34] Overall, the functionalization of caged anilines directly alters rates of COS/H$_2$S release from DTS-based donors, and the ability to control tuning of these releasing kinetics merits future investigation. By contrast, we observed the caging of alkyl amines resulted in significantly slower rates of H$_2$S release relative to DTS-caged anilines with tBuDTS and EtDTS displaying the fastest and slowest rates of H$_2$S release, respectively (Figure 3b). We reasoned that inductively donating alkyl amines likely stabilize the COS-releasing thiocarbamic intermediates leading to a decrease in H$_2$S-releasing kinetics.

To further investigate the differences between aryl and alkyl amine substitution, we used density functional theory (DFT) to examine the potential energy surface for COS release from
PhDTS and AlkylDTS compounds. In these systems, we used methyl thiol (MeSH) to simplify possible protonation states of non-participating functional groups during the reaction. Calculations were performed using Gaussian 09 at the B3LYP/6–311 + + G(d,p) level of theory applying the IEF-PCM water solvation model (Figure 4).

For PhDTS, we found that the initial nucleophilic attack by the thiolate was the highest barrier (21.7 kcal mol⁻¹) on the reaction coordinate and dethiocarboxylation of the thiocarbamic acid intermediate was only moderately endothermic (+3.2 kcal mol⁻¹) with respect to the starting materials. By contrast, although the AlkylDTS compounds showed similar activation barriers for the initial attack by thiolate (23.5–26.8 kcal mol⁻¹), the activation barrier for the final dethiocarboxylation varied significantly as a function of the alkyl group. The highest activation barrier for dethiocarboxylation was found for the EtDTS compound (+29.8 kcal mol⁻¹), but this barrier decreased with the increasing donating ability of iPrDTS (+27.5 kcal mol⁻¹), and tBuDTS (+20.9 kcal mol⁻¹); all of which were competitive with the activation barriers for initial thiol attack on the DTS motif. These relative energetic barriers are consistent with the observed rates of COS/H₂S release from the AlkylDTS compounds. Moreover, these results suggest that the inductive contributions, rather than the steric bulk differences of the alkyl substituents, have a larger impact on the release of COS from thiocarbamic acid intermediates. Taken together, the combination of experimental and computational data demonstrates the ability to tune H₂S/COS release from this scaffold by simple structural modifications. More broadly, these results provide guidance for controlling the COS/H₂S release rate from donor motifs that proceed through a thiocarbamic acid intermediate prior to COS extrusion.

Conclusions

We demonstrated the use of DTS-based compounds to serve as COS/H₂S donors in the presence of thiols without the formation of electrophilic byproducts. Reactivity studies using PhDTS as a model compound were used to investigate COS/H₂S release as a function of biological nucleophiles and thiol identity. By modifying the structure of the amine payloads, we also demonstrated that the rate of COS/H₂S release from DTS-based donors can be modified by simple structural modifications. The results from DFT calculations has shed light on the impact of amine identity on COS release from thiocarbamic acids and provides a foundation to guide future work on this reactive intermediate. Specifically, this work directly elaborates on the observed reactivity differences between aryl and alkyl thiocarbamates as COS-releasing motifs, which provides fundamental information upon which to expand the utility of these donors. The simple synthetic conditions and unique reactivity of this donor scaffold would readily allow for the incorporation amine-based payloads including fluorophores and known therapeutics to provide COS-based H₂S fluorescent donors and prodrugs.

Figure 4. Potential energy surface for COS release from PhDTS and AlkylDTS compounds. Calculations were performed using Gaussian 09 at the B3LYP/6–311 + + G(d,p) level of theory applying the IEF-PCM water solvation model. MeSH was used as the thiol nucleophile to simplify accessible protonation states of non-participating functional groups on the thiol nucleophile.
Experimental Section

Synthesis materials and methods

Reagents were purchased from Sigma-Aldrich, Tokyo Chemical Industry, or VWR and used directly as received. Deuterated solvents were purchased from Cambridge Isotope Laboratories and used as received. $^1$H, $^{13}$C($^1$H), and $^{19}$F NMR spectra were recorded on a Bruker 500 MHz instrument. Chemical shifts were reported relative to residual proton solvent resonances. MS data was collected on a Xevo G2-XS QTof (Waters) instrument. Silica gel (SiliaFlash F60, SiIcycle, 230–500 mesh) was used for column chromatography. All air-free manipulations were performed under an inert atmosphere using standard Schlenk technique.

Synthesis

General procedure for the synthesis of thiocarbamates: This procedure has been modified from a previous report.\textsuperscript{39} In a flame-dried round bottom flask under nitrogen, sodium hydride (1.25 equiv) and N,N-dimethylethanlamime were added to anhydrous toluene (20 mL). After stirring briefly until gas evolution ceased, the desired isothiocyanate (1.0 equiv) was added dropwise (if liquid) or in a single portion (if solid). The reaction was stirred at room temperature for 3 h under nitrogen, quenched with deionized H$_2$O (30 mL), and extracted with ethyl acetate (3 × 15 mL). The combined organic extractions were washed with brine (1 × 20 mL), dried over MgSO$_4$, and concentrated under reduced pressure. The desired product was obtained following purification by column chromatography. All NMR data for these compounds was obtained at 60°C due to hindered rotation of thiocarbamates at room temperature. We note the alkyl thiocarbamates displayed hindered rotation at 60°C giving rise to two sets of peaks corresponding to the E and Z isomers.

General procedure for the synthesis of dithiouacucinolinyls: This procedure has been modified from a previous report.\textsuperscript{39} To a flame-dried round bottom flask under nitrogen, chlorocarbonylsulfonyl chloride (1.0 equiv) was added to anhydrous DCM (20 mL). In a separate vial, the desired thiocarbamate (1.0 equiv) was dissolved in anhydrous DCM (1 mL) and added dropwise to the reaction. The reaction mixture was stirred at room temperature for 1 h, after which it was quenched with 1 M HCl (15 mL). The organic layer was separated and washed with deionized water (2 × 20 mL) and brine (1 × 20 mL). The resultant solution was dried over MgSO$_4$ and concentrated under reduced pressure. The desired product obtained by purification via preparative thin layer chromatography.

H$_2$S detection materials and methods

Phosphate buffered saline (PBS) tablets (1X, CalBioChem) were used to prepare buffered solutions (140 mM NaCl, 3 mM KCl, 10 mM phosphate, pH 7.4) in deionized water. Buffer solutions were sparged with nitrogen to remove dissolved oxygen and stored in an Innovative Atmosphere nitrogen-filled glovebox. Donor stock solutions (in acetonitrile) were prepared inside a nitrogen-filled glovebox immediately before use. Trigger stock solutions (in PBS) were freshly prepared in an N$_2$-filled glovebox immediately before use. CA stock solutions (in PBS) were freshly prepared in a nitrogen-filled glovebox immediately before use.

General procedure for measuring H$_2$S release via methylene blue assay (MBA)

Scintillation vials containing 20 mL of 10 mM PBS (pH 7.4) were prepared in a nitrogen-filled glovebox. To these solutions, 20 mL of 500 mM analyte stock solution and 50 μL of 10 mg mL$^{-1}$ CA were added for final concentrations of 500 μM and 25 μg mL$^{-1}$ respectively. While stirring, solutions were allowed to thermally equilibrate in heating block set at 25°C for approximately 20–30 min. Immediately prior to donor addition, 0.5 mL solutions of methylene blue cocktail were prepared in disposable 1.5 mL cuvettes. The methylene blue cocktail solution contains: 200 μL of 30 mM FeCl$_3$ in 1.2 M HCl, 200 μL of 20 mM N,N-dimethyl-p-phenylene diamine in 7.2 M HCl, and 100 μL of 1 % (w/v) Zn(OAc)$_2$. To begin an experiment, 20 μL of 25 mM donor stock solution was added for a final concentration of 25 μM. At set time points after the addition of donor, 500 μL reaction aliquots were added to the methylene blue cocktail solutions and incubated for 1 h at room temperature shielded from light. Absorbance values at 670 nm were measured 1 h after addition of reaction aliquot. Each experiment was performed in quadruplicate unless stated otherwise. UV/Vis spectra were acquired on an Agilent Cary 60 UV/Vis spectrophotometer equipped with a Quantum Northwest TC-1 temperature controller set at 25 ± 0.05°C.

Computational methods

All structures were initially constructed, and optimized using the UFF force field as implemented, in Avogadro.\textsuperscript{37} The resultant structures were further optimized using the unrestricted hybrid GGA functional, B3LYP, as implemented in Gaussian 09,\textsuperscript{38} with a triple zeta basis set that includes diffuse and polarization functions on heavy atoms, 6–311+G*. A pseudosolvant polarizable continuum model for water was used to account for solvation effects. Attackng thiols were modeled as methyl thiol to reduce computational expense.

Transition state searches were carried out at the same level of theory as ground state structures. First, a potential energy surface scan of the active reaction coordinate was used to obtain a good starting point for the ultimate transition state search algorithm. Vibrational analysis confirmed a single imaginary frequency corresponding to the direction of bond formation or breaking for each activated complex. No transition state was found for thiol disulfide exchange, which could indicate a barrierless transition, or a shallow potential energy surface with a loose transition state. Biologically relevant thiols, such as cysteine, may undergo a more sterically hindered attack when compared to the methyl thiol employed in this model and may experience a more defined transition state and activation barrier.

Use of Dithiasuccinoyl-Caged Amines Enables COS/H₂S Release Lacking Electrophilic Byproducts

No more electrophilic byproducts! The use of dithiasuccinoyl (DTS)-caged amines provides access to COS-based H₂S donors that can be activated in the presence of biological thiols including cysteine and reduced glutathione to generate two equivalents of COS/H₂S and release an amine-based payload. These donor compounds provide researchers with chemical tools to further probe the role of reactive sulfur species in biology.

The thiol-mediated reduction of dithiasuccinoyl groups was harnessed to develop a method for controlled carbonyl sulfide (COS) generation under buffered aqueous conditions. This reactivity generates two equivalents of COS and does not result in formation of electrophilic byproducts such as (imino)quinone methides. The rate of COS generation can be tuned as function of amine identity, and theoretical investigations provide key insights into COS release from thiocarbamate intermediates. For more information, see the Full Paper by M. D. Pluth and co-workers on page ff.
