- Feynman Diagrams
- Electromagnetic Interactions
- Renormalization and Gauge Invariance
- Weak and Electroweak Interactions
- Lepton Flavors and Decays
- Lepton Universality
- Neutrinos
- Neutrino Oscillations
Quantum Picture of Interactions

• Quantum Theory views action at a distance through the exchange of quanta associated with the interaction
• These exchanged quanta are virtual and can “violate” the conservation laws for a time defined by the Uncertainty Principle:
  \[ \Delta E \Delta t \equiv \hbar \]
Yukawa Theory

- During the 1930’s, Yukawa was working on understanding the short range nature of the nuclear force ($R \approx 10^{-15} m$)
- He postulated that this was due to the exchange of massive quanta which obey the Klein-Gordon eqtn:

$$\frac{\partial^2 \psi}{\partial t^2} = c^2(\nabla^2 - \frac{m^2 c^2}{\hbar^2}) \psi$$
Yukawa Theory

\[ \frac{\partial^2 \psi}{\partial t^2} = c^2 (\nabla^2 - \frac{m^2 c^2}{\hbar^2}) \psi \]

for a static potential, this becomes:

\[ \nabla^2 \psi = \left( \frac{m^2 c^2}{\hbar^2} \right) \psi \]

We can interpret \( \psi \) as the potential \( U(r) \) and solve for \( U \):

\[ U(r) = g_0 e^{-r/R} / 4\pi r, \]

where \( R = \hbar/mc \),

and \( g_0 \) is a constant (the strength)
Yukawa Theory

The range of the nuclear force was known, \[ R \approx 10^{-15} \text{m} \]

Therefore, the mass of this new exchange particle could be predicted:
\[ R = \frac{\hbar}{mc}, \]
\[ mc^2 = \frac{\hbar c}{R} \approx 200 \text{ MeV-fm/1 fm} \approx 200 \text{ MeV} \]

- The pion with mass 140 MeV/c^2 was discovered in 1947! (the muon was discovered in 1937 and mis-identified as Yukawa’s particle, the “mesotron”)
- We now realize that this interaction is actually a residual interaction, so Yukawa was a bit fortunate to find a particle with the predicted mass
The rate for a particular interaction mediated by boson exchange is proportional to the “propagator” squared, where the “propagator” is written as:

\[ f(q) = \frac{g_0 g}{q^2 + m^2}, \]

where \( q^2 = (\Delta p)^2 - (\Delta E)^2 \), is the 4-momentum transfer

\[ \Delta p = p_3 - p_1 = p_2 - p_4 \]
\[ \Delta E = E_3 - E_1 = E_2 - E_4 \]
This “propagator” can be derived by taking the Fourier transform of the potential:

\[ f(q) = g \int U(r) \, e^{i\mathbf{q} \cdot \mathbf{r}} \, dV, \quad U(r) = g_0 \, e^{-r/R} / 4\pi r \]

Therefore, the “propagator” describes the potential in momentum space.

Then, the boson “propagator” is:

\[ f(q) = g_0 g / (|q|^2 + m^2) \]

where \( q \) is the momentum of the boson, and \( m \) is its mass.
The “propagator” can be generalized to four-momentum transfer:

\[ f(q) = \frac{g_0 g}{(q^2 + m^2)}, \]

where now \( q^2 = (\Delta p)^2 - (\Delta E)^2 \),
is the 4-momentum transfer

Rates are proportional to the propagator:

\[ W = |f|^2 \times \text{Phase Space} \ldots \]
Feynman Diagrams

• Interactions can be depicted with Feynman diagrams
  – electrons
  – photons
  – positrons
    • (equivalent to electron moving backward in time)

  – electron emits a photon
    \[ A \sim e \]
  – electron absorbs a photon
    \[ A \sim e \]
Feynman Diagrams

• Virtual particles
  – lines joining vertices represent virtual particles (undefined mass)

• Vertices are represented by coupling constants, and virtual particles by propagators
Electromagnetic Interactions

• The fine structure constant specifies the strength of the EM interaction between particle and photons:
  \[ \alpha = \frac{e^2}{4\pi \hbar c} = \frac{1}{137.0360} \ldots \]

• Emission and absorption of a photon represents the basic EM interaction

  vertex amplitude = \( \sqrt{\alpha} = e \)

• cannot occur for free particle
Electromagnetic Interactions

• Coulomb scattering between two electrons:

  ![Coulomb scattering diagram]

• Amplitude: \( \alpha / q^2 \)
• Cross Section = \(|\text{Amp}|^2 \sim \alpha^2 / q^4\)
  – the Rutherford scattering formula
Electromagnetic Interactions

• Bremstrahlung:
  – electron emits photon in field of the nucleus

  \[ \sim \alpha^3 Z^2 \]

– cross section: \[ \sim \alpha^3 Z^2 \]
Electromagnetic Interactions

- Pair production ($\gamma \to e^+e^-$)

\[ \text{cross section: } \sim \alpha^3 Z^2 \]

- This process is closely related to bremsstrahlung ("crossed diagrams")
Electromagnetic Interactions

• Higher order processes
  – the diagrams we have seen so far are leading order diagrams, but the rate for a process will be the sum of all orders:
  – For example, Bhabha scattering: $e^+e^- \rightarrow e^+e^-$
    • leading order:
    • higher order:
Electromagnetic Interactions

• Example of higher order processes: the electron magnetic moment
  – lowest order:
  – higher order:

Correction $\sim e^2 \sim \alpha$  $\sim \alpha^2$  $\sim \alpha^2$
Electromagnetic Interactions

• Electron magnetic moment:
  – a Dirac electron has a magnetic moment of
    \[ \mu = g \mu_B s, \quad s = 1/2 \quad g = 2 \quad \mu_B = e\hbar/mc \]

  (g-2)/2 is the anomaly due to higher order terms

\[ (g-2)^{\text{th}}/2 = 0.5 \left( \frac{\alpha}{\pi} \right) - 0.32848 \left( \frac{\alpha}{\pi} \right)^2 + 1.19 \left( \frac{\alpha}{\pi} \right)^3 + .. \]
\[ = (115965218.085 \pm 0.076) \times 10^{-11} \]

experiment = (115965218.076 \pm 0.027) \times 10^{-11}

this measurement provides very accurate value for the fine structure constant
\[ = 1/137.035999074(44) \]
Muon g-2

\[ \mu = g \mu_B s, \]

\[ s = \frac{1}{2} \quad g = 2 \]

\[ \mu_B = \frac{e}{2mc} \]

\[ a = \frac{(g-2)}{2} \]

\[ a_{\mu}^{\exp} - a_{\mu}^{\text{SM}} = (29.6 \pm 8.1) \times 10^{-10} \]

\[ \Rightarrow 3.6 \text{ "standard deviations"} \]

18
g-2 could mean New Physics?

Supersymmetric particles (Marciano, Munich, 2011)

- Most likely (popular?)
- \( a_\mu(\text{SUSY}) = \text{sgn}(\mu) \times 10^{-11} \left( \frac{100\text{GeV}}{m_{\text{SUSY}}} \right)^2 \tan \beta \)
- \( \text{sgn}(\mu) = +, \tan \beta = 3 - 40, m_{\text{SUSY}} = 100 - 500 \text{ GeV} \)
- If SUSY: \( \text{sgn}(\mu) + \), dark matter easier, SUSY at LHC likely, EDMS, ...

Tom Blum (UConn and RIKEN BNL Research Center)  |  Muon g – 2 Theory

J. Brau  |  Physics 661, Interactions/Weak Force/Leptons
Renormalization and Gauge Invariance

• Electron line represents “bare” electron
• Observable particles are “dressed” by “infinite” number of virtual photons:
  – logarithmically divergent
• These divergences are swept away through renormalization:
  – “Bare” electron mass and charge is always multiplied by divergent integrals. We know this product must be the physical values of the mass and charge, so we set them to be, and the divergences are removed
Renormalization and Gauge Invariance

• In order for a theory to be “renormalizable” it must satisfy local gauge invariance
  – Examples of gauge invariance are familiar in EM and quantum
    • gauge transformations of scalar and vector potential in E&M do not change physical effects
    • wavefunction can change by an arbitrary phase without altering physics
Renormalization and Gauge Invariance

- The coupling constants that appear in the theory are actually not “constants”, but “run” with energy.
  - This is due again to virtual processes
  - For example, $\alpha = 1/137$ at very low energy, but $\alpha = 1/128$ at $\sqrt{s} = M_Z$

Leptons Flavors

- The Standard Model includes massless neutrinos
  - left-handed neutrinos and RH antineutrinos
- Lepton flavors are conserved in interactions
  - $L_e, L_m, L_t$
  - mass($\mu$) = 106 MeV/c$^2$
  - mass(e) = 0.5 MeV/c$^2$
  - However $\mu \rightarrow e \gamma$ is forbidden (exp: BR < 1.2 x 10$^{-11}$)
- Neutrino oscillations are indications that the neutrinos have small masses and that flavor conservation will be violated at a small level
Lepton decays
Weak and Electroweak Interactions

• Nuclear $\beta$-decay
• Lepton conservation
• Weak due to very heavy mediating vector bosons:
  - $W^\pm$, 80 GeV/c$^2$
  - $Z^0$, 91 GeV/c$^2$
• charge-current
  - $\beta$-decay
• neutral-current
Weak Interactions

Neutrino Charged Current Interaction

Muon Decay

Σ⁺ Decay

Neutral Current
Weak and Electroweak Interactions

• Simplified picture of the Weak Interaction:
  – Propagator:
    \[ f(q) = \frac{g^2}{q^2 + M_{W,Z}^2} \]
    - for \( q^2 \ll M^2 \), \( f(q) = \frac{g^2}{M_{W,Z}^2} \)
  – Fermi’s early theory of b-decay postulated an interaction with strength \( G = 10^{-5} \), which we now recognize as \( G = \frac{g^2}{M_{W,Z}^2} = 10^{-5} \text{GeV}^{-2} \)
  – Once we recognize the origin of the weakness, we can predict the masses of the W and Z
    \[ M_{W,Z} \sim \frac{e}{\sqrt{G}} \sim \sqrt{\frac{4\pi\alpha}{G}} \sim 90 \text{ GeV} \]
  • Glashow, Weinberg, Salam (1961-8)
Lepton Decays

- **Muon decay rate**
  \[ \Gamma(\mu^- \rightarrow e^- \nu_e \nu_\mu) = K G_F^2 m_\mu^5 ; \quad \tau_\mu = 2.2 \times 10^{-6} \text{ sec} \]

- **Tau**
  \[ \Gamma(\tau^- \rightarrow e^- \nu_e \nu_\tau) = K G_F^2 m_\tau^5 ; \quad \tau_\tau = 3 \times 10^{-13} \text{ sec} \]

- **Lepton lifetime**
  \[ \tau_l = \frac{1}{\Gamma_{\text{tot}}} = \frac{B(l^- \rightarrow e^- \nu_e \nu_l)}{\Gamma(l^- \rightarrow e^- \nu_e \nu_l)} \]
  - Since \[ B(l^- \rightarrow e^- \nu_e \nu_l) = \frac{\Gamma(l^- \rightarrow e^- \nu_e \nu_l)}{\Gamma_{\text{tot}}} \]

- **Ratio**
  \[ \frac{\tau_\tau}{\tau_\mu} = \frac{B(\tau^- \rightarrow e^- \nu_e \nu_\tau)}{B(\mu^- \rightarrow e^- \nu_e \nu_\mu)} \quad (m_\mu/m_\tau)^5 = 1.36 \times 10^{-7} \]
Classification of Weak Interactions

- Weak interactions are mediated by the “intermediate bosons” $W^\pm$ and $Z^0$
- Just as the EM force between two current carrying wires depends on the EM current, the weak interaction is between two weak currents, describing the flow of conserved weak charge, $g$
  \[ j \propto \psi^* \psi \]
- Two types of interactions:
  - CC (charged current)
  - NC (neutral current)
Classification of Weak Interactions

- Weak interactions occur between all types of leptons and quarks, but are often hidden by the stronger EM and strong interactions.

  - Semi-leptonic

  - Leptonic

  - Non-leptonic
Lepton universality

- Unit of weak charge
  - all the leptons carry the same weak charge and therefore couple to the $W^\pm$ with the same strength
  - The quarks DO NOT carry the same unit of weak charge

- Muon decay

\[
\Gamma (\mu \rightarrow e\nu_e\bar{\nu}_\mu) = \frac{1}{\tau} \propto G^2 m_\mu^5
\]

\[
= \frac{G^2 m_\mu^5}{192\pi^3}
\]

- experimental: $\tau_\mu = 2.197 \times 10^{-6}$ sec
Lepton universality

- Tau decay

\[
\Gamma (\tau \to e \nu_e \bar{\nu}_\tau) = B(\tau \to e \nu \nu) \frac{1}{\tau} \propto G^2 m^5_{\tau}
\]

\[
= \frac{G^2 m^5_{\tau}}{192\pi^3}
\]

- \(B(\tau \to e \nu \nu) = 17.80 \pm 0.06\%\)

- Test universality: since \(\Gamma \sim G^2 \sim g^4\)

\[
g^4_{\tau} \propto B(\tau \to e \nu \nu) / (m^5_{\tau} \tau_{\tau})
\]

\[
\left(\frac{g_{\tau}}{g_{\mu}}\right)^4 = B(\tau \to e \nu_{e} \bar{\nu}_{\tau}) \left(\frac{m_{\mu}}{m_{\tau}}\right)^5 \left(\frac{\tau_{\mu}}{\tau_{\tau}}\right)
\]
Lepton universality

- Test universality:

\[
\left( \frac{g_\tau}{g_\mu} \right)^4 - B(\tau \rightarrow e^{-} \nu_{e} \bar{\nu}_{\tau}) \left( \frac{m_\mu}{m_\tau} \right)^5 \left( \frac{\tau_\mu}{\tau_\tau} \right)
\]

With \( \tau_\mu = 2.197 \times 10^{-6} \text{ s} \), \( \tau_\tau = (291.0 \pm 1.5) \times 10^{-15} \text{ s} \), \( m_\mu = 105.658 \text{ MeV} \), \( m_\tau = 1777.0 \text{ MeV} \) and \( B(\tau \rightarrow e^{-} \nu_{e} \bar{\nu}_{\tau}) = 17.80 \pm 0.06\% \)

\[
\frac{g_\tau}{g_\mu} = 0.999 \pm 0.003
\]

\[
\frac{g_\mu}{g_e} = 1.001 \pm 0.004
\]
Lepton universality

- Lepton universality also holds for the Z couplings:

\[ Z^0 \rightarrow e^+e^- : \mu^+\mu^- : \tau^+\tau^- = 1 : 1.000 \pm 0.004 : 0.999 \pm 0.005 \]

- From the muon lifetime we can compute the Fermi constant, \( G \):

\[ \frac{G}{(\hbar c)^3} = 1.1664 \times 10^{-5} \text{ GeV}^{-2} \]
Introduction to Neutrinos

Neutrinos could contribute significantly to the total energy density of the Universe if they have a mass in the eV range.

SNO (Sudbury Neutrino Observatory) interactions in heavy water sensitive to neutral current interactions

SNO Measurements

Charged Current Reaction ($D_2O$):

\[ \nu_e + d \rightarrow p + p + e^- \quad E_{\text{thres}} = 1.4 \text{ MeV} \]  

- $\nu_e$ energy spectrum (distortion $\Rightarrow$ MSW effect)
- Some directional sensitivity ($1 - 1/3 \cos \theta_e$)

Neutral Current Reaction ($D_2O$):

\[ \nu_x + d \rightarrow \nu_x + p + n \quad E_{\text{thres}} = 2.2 \text{ MeV} \]  

- Total solar $^8B$ neutrino flux (active neutrinos)

\[
\frac{\text{Ratio}}{\text{NC}} = \frac{\nu_e \text{ flux}}{(\nu_e + \nu_\mu + \nu_\tau) \text{ flux}}
\]

Elastic Scattering Reaction ($D_2O.H_2O$):

\[ \nu_x + e^- \rightarrow \nu_x + e^- \quad E_{\text{thres}} = 0 \text{ MeV} \]  

- Low counting rate
- Directional sensitivity (very forward peaked)

\[
\frac{\text{Ratio}}{\text{ES}} = \frac{\nu_e \text{ flux}}{0.86 \nu_e + 0.14(\nu_\mu + \nu_\tau) \text{ flux}}
\]

- The values for Chlorine and Gallium experiments are given in SNU.
- The values for Cerenkov experiments are given in units of $10^{10}$ counts/m² s.
- The errors for the relative values correspond to experimental and theoretical errors, respectively, with the statistical and systematic errors added quadratically. Some of the relative values are based on my own calculation from the published results.

from “The Ultimate Neutrino Page”
http://cupp.oulu.fi/neutrino/nd-sol2.html
Neutrino Oscillations

Two possible solutions to the Solar Neutrino Problem:
1. The Standard Solar Model is wrong
cross sections, temperature, whatever
2. Neutrinos behave differently
decky, transform, whatever

If the neutrinos are massless, they will not decay
But if the neutrinos have mass they may decay:
eg. $\nu_\alpha \rightarrow \nu_\beta + \gamma$
but the estimate of this rate is very small in the SM
Another possibility, if they have mass, the different flavors may mix
weak-interaction and mass eigenstates may be different
Neutrino Oscillations

\[ |\nu_f > = \sum_m c_{fm} |\nu_m > \]

Consider two flavors

\[
\begin{pmatrix}
\nu_\mu \\
\nu_e
\end{pmatrix} =
\begin{pmatrix}
\cos \theta & \sin \theta \\
-\sin \theta & \cos \theta
\end{pmatrix}
\begin{pmatrix}
\nu_1 \\
\nu_2
\end{pmatrix}
\]

\[ |\nu_e(t) > = -\sin \theta e^{-iE_1 t} |\nu_1 > + \cos \theta e^{-iE_2 t} |\nu_2 > \]

\[ E_i = p + \frac{m_i^2}{2p} \]

\[ P(\nu_e \to \nu_e) = 1 - \sin^2 (2\theta) \sin^2 \left[ \frac{1}{2} (E_2 - E_1) t \right] \]

\[ P(\nu_e \to \nu_\mu) = \sin^2 (2\theta) \sin^2 \left[ \frac{\Delta m^2}{4E} t \right] \]

since \( m_i \ll p \)
Neutrino Oscillations

\[ A = \sin^2(2\theta) \]
\[ L_\nu = \frac{4\pi E h}{\Delta m^2 c^3} \]

\[ L_\nu = 2.48 \left( \frac{E}{1 \text{ MeV}} \right) \left( \frac{1 \text{ eV}^2}{\Delta m^2} \right) \text{ metres.} \]
Mixing Matrix

\[ \nu_{L}(x) = \sum_{j} U_{lj} \nu_{jL}(x), \quad l = e, \mu, \tau, \]

where \( \nu_{jL}(x) \) is the LH component of the field of \( \nu_j \) possessing a mass \( m_j \) and \( U \) is a unitary matrix - the neutrino mixing matrix \([1,17,18]\). The matrix \( U \) is often called the Pontecorvo-Maki-Nakagawa-Sakata (PMNS) or Maki-Nakagawa-Sakata (MNS) mixing matrix. Obviously, Eq. (13.1) implies that the individual lepton charges \( L_l, l = e, \mu, \tau, \) are not conserved.

\[
U = \begin{pmatrix}
\nu_{1} & \nu_{2} & \nu_{3} \\
\nu_{e} & c_{12}c_{13} & s_{12}c_{13}e^{i\delta} \\
\nu_{\mu} & -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} \\
\nu_{\tau} & s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -s_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} \\
\end{pmatrix}
\times \text{diag}(e^{i\alpha_{1}/2}, e^{i\alpha_{2}/2}, 1)
\]
Mixing Matrix

\[
\begin{pmatrix}
\nu_e \\
\nu_{\mu} \\
\nu_{\tau}
\end{pmatrix}
= \begin{pmatrix}
c_{12} & s_{12} & 0 \\
-s_{12} & c_{12} & 0 \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
1 & 0 & 0 \\
0 & c_{23} & s_{23} \\
0 & -s_{23} & c_{23}
\end{pmatrix}
\times
\begin{pmatrix}
c_{13} & 0 & s_{13}e^{-i\delta} \\
0 & 1 & 0 \\
-s_{13}e^{i\delta} & 0 & c_{13}
\end{pmatrix}
\begin{pmatrix}
e^{i\alpha_1/2} & 0 & 0 \\
0 & e^{i\alpha_2/2} & 0 \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
\nu_1 \\
\nu_2 \\
\nu_3
\end{pmatrix}
\]

\[c_{ij} \equiv \cos \theta_{ij}, \quad s_{ij} \equiv \sin \theta_{ij}, \quad \{\delta, \alpha_1, \alpha_2\} \equiv \text{CP-Violating Phases}\]
Neutrino Oscillations

Experiments:

Reactor
- disappearance of electron neutrino
  since muon cannot be produced by MeV neutrinos

Accelerator
- appearance of electron neutrino,
  from muon neutrino beam

Solar
- disappearance of electron neutrino

Atmospheric
- electron and muon neutrinos produced in atmosphere by cosmic rays

Atmospheric Neutrinos

\[ p/n + N \rightarrow \pi^+ / K^+ + \ldots \]
\[ \pi^+ / K^+ \rightarrow \mu^+ \nu_\mu \]
\[ \mu^+ \rightarrow e^+ \bar{\nu}_\mu + \nu_e, \]
\[ p/n + N \rightarrow \pi^- / K^- + \ldots \]
\[ \pi^- / K^- \rightarrow \mu^- + \bar{\nu}_\mu \]
\[ \mu^- \rightarrow e^- + \nu_\mu + \bar{\nu}_e \]

\[
\frac{\varphi_{\nu_\mu} + \varphi_{\bar{\nu}_\mu}}{\varphi_{\nu_e} + \varphi_{\bar{\nu}_e}} = 2
\]

\(E_\nu\) has broad peak \(\sim 0.1\) GeV

oscillation will depend on azimuth due to \(L\) dependence

\[ L_{\text{max}} \approx 10^4 \text{ km} \Rightarrow \Delta m^2 \sim 10^{-5} \text{ eV}^2 \]

\[ L_\nu = 2.48 \left( \frac{E}{1 \text{ MeV}} \right) \left( \frac{1 \text{ eV}^2}{\Delta m^2} \right) \text{ metres.} \]
Atmospheric Neutrinos

$$P(\nu_\mu \to \nu_\mu) = 1 - \sin^2(2\theta) \sin^2 \left( \frac{\Delta m^2}{4E} t \right)$$

$$\sin^2 \theta \sim 1, \, \Delta m^2 \sim 2.2 \times 10^{-3} \text{eV}^2$$

$$A = \sin^2(2\theta)$$

$$L_\nu = \frac{4\pi E \mu}{\Delta m^2 c^3}$$
**Neutrino Oscillations**

Figure 14.6: The 90% CL allowed regions from $\nu_\mu$ disappearance results: T2K 2013 [23], T2K2011 [22], Super-Kamiokande [138], and MINOS [143]. The MINOS contour was obtained by assuming identical neutrino and antineutrino oscillation parameters. This figure is taken from Ref. 23.

14.6. Measurements of $\theta_{13}$

Reactor $\bar{\nu}_e$ disappearance experiments with $L \sim 1$ km, $\langle E \rangle \sim 3$ MeV are sensitive to $\sim E/L \sim 3 \times 10^{-3}$ eV$^2 \sim |\Delta m^2_{\odot}|$. At this baseline distance, the reactor $\bar{\nu}_e$ oscillations driven by $\Delta m^2_{\odot}$ are negligible. Therefore, as can be seen from Eq. (14.22) and Eq. (14.24), $\theta_{13}$ can be directly measured. A reactor neutrino oscillation experiment at the Chooz

$$P(\nu_e \to \nu_e) = P(\bar{\nu}_e \to \bar{\nu}_e) \approx 1 - 2|U_{e3}|^2 \left(1 - |U_{e3}|^2\right) \left(1 - \cos \frac{\Delta m^2_{31}}{2p} L\right),$$

(14.22)

$$\sin^2 \theta_{13} = |U_{e3}|^2, \quad s^2_{23} = \sin^2 \theta_{23} = \frac{|U_{\mu 3}|^2}{1 - |U_{e3}|^2},$$

$$c^2_{23} = \cos^2 \theta_{23} = \frac{|U_{\tau 3}|^2}{1 - |U_{e3}|^2}.$$  

(14.24)
# Neutrino Oscillations

Table 14.7: The best-fit values and $3\sigma$ allowed ranges of the 3-neutrino oscillation parameters, derived from a global fit of the current neutrino oscillation data (from [174]). The values (values in brackets) correspond to $m_1 < m_2 < m_3$ ($m_3 < m_1 < m_2$). The definition of $\Delta m^2$ used is: $\Delta m^2 = m_3^2 - (m_2^2 + m_1^2)/2$. Thus, $\Delta m^2 = \Delta m_{31}^2 - \Delta m_{21}^2/2 > 0$, if $m_1 < m_2 < m_3$, and $\Delta m^2 = \Delta m_{32}^2 + \Delta m_{21}^2/2 < 0$ for $m_3 < m_1 < m_2$.
