A rough outline of all six lectures

- The beginning: The C*-algebra of a group.
- Actions of finite groups on C*-algebras and examples.
- Crossed products by actions of finite groups: elementary theory.
- More examples of actions.
- Crossed products by actions of finite groups: Some examples.
- The Rokhlin property for actions of finite groups.
- Examples of actions with the Rokhlin property.
- Crossed products of AF algebras by actions with the Rokhlin property.
- Other crossed products by actions with the Rokhlin property.
- The tracial Rokhlin property for actions of finite groups.
- Examples of actions with the tracial Rokhlin property.
- Crossed products by actions with the tracial Rokhlin property.
- Applications of the tracial Rokhlin property.

The Rokhlin property

Recall the Rokhlin property (with exact permutation of the projections): Let \( A \) be a unital C*-algebra, and let \( \alpha : G \to \text{Aut}(A) \) be an action of a finite group \( G \) on \( A \). Then \( \alpha \) has the Rokhlin property if for every finite set \( F \subset A \) and every \( \varepsilon > 0 \), there are mutually orthogonal projections \( e_g \in A \) for \( g \in G \) such that:

1. \( \alpha_g(e_h) = e_{gh} \) for all \( g, h \in G \).
2. \( \|e_g a - a e_g\| < \varepsilon \) for all \( g \in G \) and all \( a \in F \).
3. \( \sum_{g \in G} e_g = 1 \).

**Theorem**

Let \( A \) be a unital AF algebra. Let \( G \) be a finite group, and let \( \alpha : G \to \text{Aut}(A) \) have the Rokhlin property. Then \( C^*(G, A, \alpha) \) is AF.
Crossed products of AF algebras by Rokhlin actions

### Theorem
Let $A$ be a unital AF algebra. Let $G$ be a finite group, and let $\alpha: G \to \text{Aut}(A)$ have the Rokhlin property. Then $C^*(G, A, \alpha)$ is AF.

The idea of the proof: We need only consider a finite set $S \subset C^*(G, A, \alpha)$ of the form $S = F \cup \{u_g : g \in G\}$, with $F \subset A$ finite and $u_g \in C^*(G, A, \alpha)$ the standard unitary corresponding to $g \in G$. We chose a family $(e_g)_{g \in G}$ in $A$ of Rokhlin projections for $\alpha$, $F$, and $\delta > 0$ (depending on $\varepsilon$). That is,
\[ \alpha_g(e_h) = e_{gh} \text{ for all } g, h \in G. \]
\[ \|e_g a - a e_g\| < \delta \text{ for all } g \in G \text{ and all } a \in F. \]
\[ \sum_{g \in G} e_g = 1. \]
(In particular, the projections $e_g$ are orthogonal.)
We took $D_0 = \bigoplus_{g \in G} e_g A e_g \subset A$, which is a $G$-invariant unital subalgebra of $A$ containing $F$ to within $\varepsilon$. Then $D = C^*(G, D_0, \alpha) \subset C^*(G, A, \alpha)$ is a unital subalgebra which contains $F$ to within $\varepsilon$ and exactly contains $u_g$ for $g \in G$. Thus $D$ contains $S$ to within $\varepsilon$. Also, $D \cong M_n(e_1 A e_1)$, which is AF.
So finite sets in $C^*(G, A, \alpha)$ can be approximated by AF subalgebras, hence by finite dimensional subalgebras. Thus $C^*(G, A, \alpha)$ is AF.

A distillation of the proof

### Proposition
Let $A$ be a unital $C^*$-algebra. Let $G$ be a finite group; set $n = \text{card}(G)$. Let $\alpha: G \to \text{Aut}(A)$ have the Rokhlin property. Let $S \subset C^*(G, A, \alpha)$ be a finite set and let $\varepsilon > 0$. Then there exist a projection $p \in A$ and a unital subalgebra $D \subset C^*(G, A, \alpha)$ such that:
\begin{itemize}
  \item $D \cong M_n(p A p)$.
  \item $\text{dist}(b, D) < \varepsilon$ for all $b \in S$.
\end{itemize}

### Proposition
Let $B$ be a unital $C^*$-algebra. Suppose that there is a unital AF algebra $A$ such that, for every finite set $S \subset B$ and every $\varepsilon > 0$, there exist a projection $p \in A$, $n \in \mathbb{N}$, and a unital subalgebra $D \subset B$ such that:
\begin{itemize}
  \item $D \cong M_n(p A p)$.
  \item $\text{dist}(b, D) < \varepsilon$ for all $b \in S$.
\end{itemize}
Then $B$ is AF.

Other structural consequences of the Rokhlin property

Informally, we have:
\begin{itemize}
  \item Let $A$ be a unital $C^*$-algebra. Let $G$ be a finite group, and let $\alpha: G \to \text{Aut}(A)$ have the Rokhlin property. Then $C^*(G, A, \alpha)$ can be locally approximated by matrix algebras over corners of $A$.
  \item Let $B$ be a unital $C^*$-algebra which can be locally approximated by matrix algebras over corners of AF algebras. Then $B$ is AF.
\end{itemize}

The recognition that the original proof could be interpreted this way is due to Hiroyuki Osaka.

There are other properties besides “AF” for which (2) works. We list some results on the next slide.

Other structural consequences (continued)

Crossed products by actions of finite groups with the Rokhlin property preserve various other classes of $C^*$-algebras. In many cases, the proofs follow the idea of the previous slide. Some examples of such classes:
\begin{itemize}
  \item Simple unital $C^*$-algebras. (Exercise: Prove this.)
  \item Various classes of unital but not necessarily simple countable direct limit $C^*$-algebras using semiprojective building blocks, such as AI algebras and AT algebras. (With Osaka.)
  \item Simple unital AH algebras with slow dimension growth and real rank zero. (With Osaka.) (Open problem: Is it true without simplicity?)
  \item $D$-absorbing separable unital $C^*$-algebras for a strongly self-absorbing $C^*$-algebra $D$. (Hirshberg-Winter.)
  \item Separable nuclear unital $C^*$-algebras whose quotients all satisfy the Universal Coefficient Theorem. (With Osaka.)
  \item Separable unital approximately divisible $C^*$-algebras. (Hirshberg-Winter.)
  \item Unital $C^*$-algebras with the ideal property and unital $C^*$-algebras with the projection property. (With Pasnicu.)
\end{itemize}
Freeness and the Rokhlin property

A free action of a finite group on the Cantor set $X$ has the Rokhlin property. (That is, the corresponding action on $C(X)$ has the Rokhlin property.) This was an exercise in Lecture 3.

A free action on a connected space $X$ doesn’t, since there are no nontrivial projections in $C(X)$. (We won’t discuss this further, but such an action does have a “higher dimensional Rokhlin property” as defined by Hirshberg, Winter, and Zacharias, or the “$X$-Rokhlin property”, as in work with Hirshberg.)

We consider mostly simple C*-algebras with many projections. Recall that irrational rotation algebras, UHF algebras, and Cuntz algebras all have real rank zero. (That is, every selfadjoint element is a limit of selfadjoint elements with finite spectrum: a limit of linear combinations of orthogonal projections.) (If there are not enough projections, finite group actions are less well understood, although there has been significant recent progress. In the nonsimple case, rather little is known.)

The Rokhlin property and $A_\theta$

Let $\theta \in \mathbb{R} \setminus \mathbb{Q}$, and recall that $A_\theta$ is generated by unitaries $u$ and $v$ satisfying $uv = e^{2\pi i \theta} vu$. This algebra is a noncommutative version of $C(S^1 \times S^1)$. It is simple (this requires $\theta \notin \mathbb{Q}$), and has a unique tracial state $\tau_\theta$ (this also requires $\theta \notin \mathbb{Q}$), which should be thought of as the analog of Lebesgue measure on $S^1 \times S^1$. The range of $\tau_\theta$ on projections in $A_\theta$ is $\mathbb{Z} + \theta \mathbb{Z} \cap [0,1]$, and the range of $(\tau_\theta)_*: K_0(A_\theta) \to \mathbb{R}$ is $\mathbb{Z} + \theta \mathbb{Z}$. (For $\theta \in \mathbb{Q}$, there are many tracial states, but they all satisfy these conditions.) Also, $A_\theta$ has many projections; in fact, $A_\theta$ has real rank zero (like $C(X)$ when $X$ is the Cantor set).

Further recall the action $\alpha: \mathbb{Z}_n \to \text{Aut}(A_\theta)$ generated by

$u \mapsto e^{2\pi i/n} u$ and $v \mapsto v$.

This is a noncommutative version of the free action of $\mathbb{Z}_n$ on $S^1 \times S^1$ given by rotation by $e^{2\pi i/n}$ in the first coordinate. Since $A_\theta$ has real rank zero, one would hope that $\alpha$ has the Rokhlin property.

Tracial states and the Rokhlin property

Motivation: Recall that a tracial state on a C*-algebra $A$ is a state $\tau$ on $A$ such that $\tau(ab) = \tau(ba)$ for all $a, b \in A$. Any tracial state $\tau$ induces a homomorphism $\tau_*: K_0(A) \to \mathbb{R}$, given by extending $\tau$ to $M_n(A)$ for all $n$, and setting $\tau_*([p]) = \tau(p)$ for any projection $p \in M_n(A)$. See the K-theory lectures, but the basic point is that if $s^*s = p$ and $ss^* = q$, then the trace condition implies $\tau(p) = \tau(q)$.

Suppose $A$ has a unique tracial state. (This is true for both UHF algebras and irrational rotation algebras.) Let $G$ be finite, and let $\alpha: G \to \text{Aut}(A)$ have the Rokhlin property. In the version with exact permutation of the projections, take $\varepsilon = 1$ and $F = \emptyset$. (In fact, $\varepsilon$ and $F$ can be arbitrary.)

We get projections $e_g$ such that, in particular:

- $\alpha(e_1) = e_g$ for all $g \in G$.
- $\sum_{g \in G} e_g = 1$.

Since $\tau$ is unique, we have $\tau \circ \alpha_g = \tau$ for all $g \in G$. So $\tau(e_g) = \tau(e_1)$. It follows that

$$\tau(e_1) = \frac{1}{\text{card}(G)}.$$

The Rokhlin property and $A_\theta$ (continued)

From two slides ago: If $A$ has a unique tracial state $\tau$, and $\alpha: G \to \text{Aut}(A)$ has the Rokhlin property, then for any family $(e_g)_{g \in G}$ in $A$ of Rokhlin projections, $\tau(e_1) = \frac{1}{\text{card}(G)}$.

From the previous slide: for $\theta \in \mathbb{R} \setminus \mathbb{Q}$, the irrational rotation algebra $A_\theta$ has a unique tracial state $\tau_\theta$, and $\tau_\theta(p) \in \mathbb{Z} + \theta \mathbb{Z}$ for all projections $p \in A_\theta$.

On $A_\theta$, we wanted $u \mapsto e^{2\pi i/n}u$ and $v \mapsto v$ to generate an action of $\mathbb{Z}_n$ with the Rokhlin property. In fact, no action of any nontrivial finite group on $A_\theta$ has the Rokhlin property! The reason is that there is no projection $e \in A_\theta$ with $\tau(e) = \frac{1}{n}$, for any $n \geq 2$.

For similar reasons, no action of $\mathbb{Z}_2$ on $D = \bigotimes_{n=1}^\infty M_3$ has the Rokhlin property. (The tracial state $\tau$ defines an isomorphism $\tau_*: K_0(D) \to \mathbb{Z}[\frac{1}{3}]$.)

There are more subtle obstructions to the Rokhlin property. For example, $M_2 \otimes \bigotimes_{n=1}^\infty M_3$ does have projections with trace $\frac{1}{2}$, but there are still no actions of $\mathbb{Z}_2$ with the Rokhlin property. (Often, one at least needs a copy of $M_{2^n}$ for every $n$. Exercise: Prove this for an action on a UHF algebra.)
Consider the Cuntz algebras $O_d$, for $d \in \{2, 3, \ldots, \infty\}$. There is no tracial state. But: The group $K_0(O_d)$ is generated by $[1]$. Therefore every automorphism of $O_d$ is the identity on $K_0(O_d)$.

It follows that if $\text{card}(G) = n$ and $\alpha : G \to \text{Aut}(O_d)$ has the Rokhlin property, then the class of a Rokhlin projection $\pi_1$ satisfies $n[\pi_1] = [1]$.

$K_0(O_\infty) = \mathbb{Z}[1]$, so there is no action of any nontrivial finite group on $O_\infty$ with the Rokhlin property.

For $\text{card}(G) = d$, a Rokhlin action of $G$ on $O_d$ was described earlier (without proof). However, for example, there is no Rokhlin action of $\mathbb{Z}_2$ on $O_3$, because $[1] \in K_0(O_3)$ generates $K_0(O_3) \cong \mathbb{Z}_2$, and so can’t be written in the form $2[\pi]$.

There are stronger cohomological obstructions to the Rokhlin property (Izumi). In fact, the Rokhlin property is very rare.

Side comment: On $A_0$, $u \mapsto e^{2\pi i/n}u$ and $v \mapsto v$ gives an action of $\mathbb{Z}_n$ with a kind of higher dimensional Rokhlin property (the version with commuting towers). However, no action of any nontrivial finite group on $O_\infty$ can even have this property (with Hirshberg).

---

**Pointwise outer actions**

For simplicity of the crossed product, a much weaker condition suffices.

**Definition**

An action $\alpha : G \to \text{Aut}(A)$ is pointwise outer if, for every $g \in G \setminus \{1\}$, the automorphism $\alpha_g$ is outer, that is, not of the form $a \mapsto \text{Ad}(u)(a) = uau^*$ for some unitary $u$ in the multiplier algebra $M(A)$ of $A$.

**Theorem (Kishimoto)**

Let $\alpha : G \to \text{Aut}(A)$ be an action of a discrete group $G$ on a simple separable C*-algebra $A$. Suppose that $\alpha$ is pointwise outer. Then $C^*(G, A, \alpha)$ is simple.

---

**Recall the Rokhlin property**

**Definition**

Let $A$ be a unital C*-algebra, and let $\alpha : G \to \text{Aut}(A)$ be an action of a finite group $G$ on $A$. We say that $\alpha$ has the Rokhlin property if for every finite set $F \subseteq A$ and every $\varepsilon > 0$, there are mutually orthogonal projections $e_g \in A$ for $g \in G$ such that:

1. $\|\alpha_g(e_h) - e_{gh}\| < \varepsilon$ for all $g, h \in G$.
2. $\|e_g.a - ae_g\| < \varepsilon$ for all $g \in G$ and all $a \in F$.
3. $\sum_{g \in G} e_g = 1$.

Crossed products by actions with the Rokhlin property are very well behaved, but the Rokhlin property is rare. Pointwise outerness is common, but not good enough. Therefore we look for an intermediate condition. It will be the tracial Rokhlin property. There are many actions which have this property.
The tracial Rokhlin property

Definition

Let $A$ be an infinite dimensional simple separable unital C*-algebra, and let $\alpha : G \to \text{Aut}(A)$ be an action of a finite group $G$ on $A$. We say that $\alpha$ has the tracial Rokhlin property if for every finite set $F \subset A$, every $\varepsilon > 0$, and every positive element $x \in A$ with $\|x\| = 1$, there are mutually orthogonal projections $e_g \in A$ for $g \in G$ such that, with $e = \sum_{g \in G} e_g$:

1. $\|\alpha_g(e_h) - e_{gh}\| < \varepsilon$ for all $g, h \in G$.
2. $\|e_g a - ae_g\| < \varepsilon$ for all $g \in G$ and all $a \in F$.
3. $1 - e$ is Murray-von Neumann equivalent to a projection in the hereditary subalgebra $xAx$ of $A$ generated by $x$.
4. $\|exe\| > 1 - \varepsilon$.

The Rokhlin property corresponds to $e = 1$.

If $A$ is finite, the last condition can be omitted. (We omit the proof.)

Subsets and exactly permuting the projections

The conditions in the definition: with $e = \sum_{g \in G} e_g$:

1. $\|\alpha_g(e_h) - e_{gh}\| < \varepsilon$ for all $g, h \in G$.
2. $\|e_g a - ae_g\| < \varepsilon$ for all $g \in G$ and all $a \in F$.
3. $1 - e$ is Murray-von Neumann equivalent to a projection in the hereditary subalgebra generated by $x$.
4. $\|exe\| > 1 - \varepsilon$.

As for the Rokhlin property, we need only consider finite subsets of a generating set for $A$.

As for the Rokhlin property, we can use equivariant semiprojectivity to replace

$$\|\alpha_g(e_h) - e_{gh}\| < \varepsilon$$

for all $g, h \in G$'

(in 1)) with

$$\|\alpha_g(e_h) = e_{gh}$$

for all $g, h \in G$.

We do this in these lectures.

Comparison: tracial rank zero

The tracial Rokhlin property was motivated by the definition of tracial rank zero (originally called “tracially AF”):

Definition

Let $A$ be a simple separable unital C*-algebra. Then $A$ has tracial rank zero if for every finite subset $F \subset A$, every $\varepsilon > 0$, and every nonzero positive element $x \in A$, there exists a nonzero projection $p \in A$ and a unital finite dimensional subalgebra $D \subset pAp$ such that:

1. $\|[a, p]\| < \varepsilon$ for all $a \in F$.
2. $\text{dist}(pap, D) < \varepsilon$ for all $a \in F$.
3. $1 - p$ is Murray-von Neumann equivalent to a projection in $xAx$.

In both definitions, the strong version (the Rokhlin property, or local approximation by finite dimensional C*-algebras) is supposed to hold only after cutting down by a “large” projection which approximately commutes with all elements of the given finite set.
An example for the tracial Rokhlin property

Here is an example for which it is fairly easy to see that the tracial Rokhlin property holds but the Rokhlin property doesn’t hold.

Take \(v_k \in M_{3^k}\) to be the unitary

\[v_k = \text{diag}(1, 1, \ldots, 1, -1, -1, \ldots, -1),\]

in which the diagonal entry 1 occurs \(\frac{1}{2}(3^k + 1)\) times and the diagonal entry \(-1\) occurs \(\frac{1}{2}(3^k - 1)\) times. Let \(\alpha\) be the order 2 automorphism

\[\alpha = \bigotimes_{k=1}^\infty \text{Ad}(v_k) \quad \text{of} \quad A = \bigotimes_{k=1}^\infty M_{3^k}.\]

It generates an action of \(\mathbb{Z}_2\) (also called \(\alpha\)). Note that \(A\) is just the \(3^\infty\) UHF algebra.

We consider the tracial Rokhlin property below, but we can see right away that \(\alpha\) does not have the Rokhlin property: by K-theory, there is no action at all of \(\mathbb{Z}_2\) on this algebra which has the Rokhlin property.

An example for the tracial Rokhlin property (continued)

\[v_k = \text{diag}(1, 1, \ldots, 1, -1, -1, \ldots, -1),\]

with \(-1\) occurring \(r(k) = \frac{1}{2}(3^k - 1)\) times and \(1\) occurring \(r(k) + 1 = \frac{1}{2}(3^k + 1)\) times, and \(\alpha\) is the \(\mathbb{Z}_2\) action on the \(3^\infty\) UHF algebra generated by \(\bigotimes_{n=1}^\infty \text{Ad}(v_k)\).

\(v_k\) is unitarily equivalent to the block unitary (in which subscripts indicate matrix sizes)

\[w_k = \begin{pmatrix} 0 & 1_{r(k)} & 0 \\ 1_{r(k)} & 0 & 0 \\ 0 & 0 & 1_1 \end{pmatrix} \in M_{3^k}.\]

(This is the direct sum of many copies of the fact, used earlier, that the matrices

\[
\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}
\]

are unitarily equivalent.) So \(\alpha\) is conjugate to \(\beta = \bigotimes_{n=1}^\infty \text{Ad}(w_k)\).

An example for the tracial Rokhlin property (continued)

We had, in \(M_{3^{n+1}}\),

\[w_{n+1}p_0w_{n+1}^{*} = p_1 \quad \text{and} \quad w_{n+1}p_1w_{n+1}^{*} = p_0,\]

and the normalized trace of \(1 - p_0 - p_1\) is less than \(\varepsilon\).

Now we take

\[e_0 = 1_{A_n} \otimes p_0, \quad e_1 = 1_{A_n} \otimes p_1 \in A_n \otimes M_{3^{n+1}} = A_{n+1}.\]

Since all elements of \(F\) have the form \(a \otimes 1_{M_{3^{n+1}}}\) with \(a \in A_n\), these projections exactly commute with the elements of \(F\).

Also, \(\tau(1 - e_0 - e_1) < \varepsilon\) because \(\tau(1 - e_0 - e_1)\) is the normalized trace of \(1 - p_0 - p_1\).

Finally, on \(A_n \otimes M_{3^{n+1}}\), the automorphism \(\beta\) has the form

\[\text{Ad}(w^{(n)} \otimes w_{n+1})\] (with \(w^{(n)} = w_1 \otimes w_2 \otimes \cdots \otimes w_n\), so

\[\beta(e_0) = e_1 \quad \text{and} \quad \beta(e_1) = e_0.\]

This proves the tracial Rokhlin property.
An example for the tracial Rokhlin property (continued)

\[ v_k = \text{diag}(1, 1, \ldots, 1, -1, -1, \ldots, -1), \]
and \( \alpha \) is the \( \mathbb{Z}_2 \)-action on the \( 3^\infty \) UHF algebra generated by \( \bigotimes_{n=1}^{\infty} \text{Ad}(v_k) \).

The matrix size is very large, and the numbers of 1’s and -1’s are very close. This looks special.

Recall from Lecture 2 the action of \( \mathbb{Z}_2 \) on \( \bigotimes_{n=1}^{\infty} M_2 \) generated by

\[ \gamma = \bigotimes_{n=1}^{\infty} \text{Ad}(v), \]
with \( v = \text{diag}(1, 1, -1) \). Rewrite \( \gamma \) as

\[ \text{Ad}(v) \otimes \text{[Ad}(v) \otimes \text{Ad}(v)] \otimes \text{[Ad}(v) \otimes \text{Ad}(v)] \otimes \cdots = \bigotimes_{n=1}^{\infty} \text{Ad}(v^{\otimes n}). \]

We have \( v_1 = v \). On the diagonal of \( v^{\otimes 2} \) there are \( 2 \cdot 2 + 1 \cdot 1 = 5 \) entries equal to 1 and \( 2 \cdot 1 + 1 \cdot 2 = 4 \) entries equal to -1. So \( v^{\otimes 2} \) is unitarily equivalent to \( v_2 \). Inductively, \( v^{\otimes n} \) is unitarily equivalent to \( v_n \). (Exercise: Prove it.) So the action \( \gamma \) has the tracial Rokhlin property.

The tracial Rokhlin property is common

The action of \( \mathbb{Z}_2 \) generated by

\[ \gamma = \bigotimes_{n=1}^{\infty} \text{Ad} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix} \]

has the tracial Rokhlin property.

In fact, it turns out to be hard to write down a product type action of \( \mathbb{Z}_2 \) using conjugation by matrices of the form

\[ \text{diag}(1, 1, \ldots, 1, -1, -1, \ldots, -1) \]

which is outer but doesn’t have the tracial Rokhlin property. In particular, the matrix sizes must go to infinity. (Example below.)

Exercise: Any product type action of \( \mathbb{Z}_2 \) is conjugate to an infinite tensor product of conjugations by matrices of the form in (1).

Some other actions with the tracial Rokhlin property

- The actions on irrational rotation algebras coming from finite subgroups of \( \text{SL}_2(\mathbb{Z}) \) have the tracial Rokhlin property. (Formulas are recalled when we see this action again in the next lecture.)
- The action of \( \mathbb{Z}_n \) on an irrational rotation algebra generated by

\[ u \mapsto e^{2\pi i/n}u \quad \text{and} \quad v \mapsto v \]

has the tracial Rokhlin property.
- The tensor flip on any UHF algebra has the tracial Rokhlin property. (Exercise: Prove this.)
- An action of a finite group on a unital Kirchberg algebra has the tracial Rokhlin property if and only if it is pointwise outer (essentially due to Nakamura).

None of the actions in (1), (2), or (3) has the Rokhlin property. In (4), most don’t have the Rokhlin property. Some proofs are complicated.

Most actions above don’t even have the right sort of higher dimensional Rokhlin property (the one with commuting towers). (The action \( u \mapsto e^{2\pi i/n}u \) and \( v \mapsto v \) does have this property.)

Some other actions with the tracial Rokhlin property

Actions with the tracial Rokhlin property, but mostly without the Rokhlin property or even its nearly as good generalization:
- Actions on \( A_0 \) from finite subgroups of \( \text{SL}_2(\mathbb{Z}) \).
- The action of \( \mathbb{Z}_n \) on an irrational rotation algebra generated by \( u \mapsto e^{2\pi i/n}u \) and \( v \mapsto v \). (It does have a higher dimensional Rokhlin property with commuting towers.)
- The tensor flip on any UHF algebra.
- Pointwise outer actions of a finite group on a unital Kirchberg algebra.

It is true (exercise: prove it) that the tracial Rokhlin property implies pointwise outerness in complete generality, but the converse is false. Counterexample without proof: The product type action of \( \mathbb{Z}_2 \) generated by

\[ \bigotimes_{n=1}^{\infty} \text{Ad}(-1, 1, 1, \ldots, 1) \]

on \( A = \bigotimes_{n=1}^{\infty} M_{2^n+1} \).

Exercise (nontrivial): Give a proof. Hint: If it had the tracial Rokhlin property, show the crossed product would have a unique tracial state. Compute the crossed product and show it actually has more than one tracial state.)
Crossed products by actions with the tracial Rokhlin property

The tracial Rokhlin property is good for understanding the structure of crossed products.

Theorem

Let $A$ be a simple separable unital C*-algebra with tracial rank zero. Let $G$ be a finite group, and let $\alpha : G \to \text{Aut}(A)$ have the tracial Rokhlin property. Then $C^*(G, A, \alpha)$ has tracial rank zero.

This is important because tracial rank zero is a hypothesis in a major classification theorem (due to Lin).

There are examples (such as the one of Elliott mentioned above) which show that this theorem fails if one weakens the condition on the action to pointwise outerness.

Appendix: The Rokhlin property and factors of type II$_1$

Let $A$ be a unital C*-algebra, an action $\alpha : G \to \text{Aut}(A)$ of a finite group $G$ on a unital C*-algebra $A$ has the Rokhlin property if for every finite set $F \subset A$ and every $\epsilon > 0$, there are projections $e_g \in A$ for $g \in G$ such that:

1. $\|\alpha_g(e_h) - e_{gh}\| < \epsilon$ for all $g, h \in G$.
2. $\|e_g a - ae_g\| < \epsilon$ for all $g \in G$ and all $a \in F$.
3. $\sum_{g \in G} e_g = 1$. (In particular, the $e_g$ are orthogonal.)

For II$_1$ factors we need:

Definition

Let $A$ be a C*-algebra with tracial state $\tau$. The trace (semi-)norm on $A$ associated to $\tau$ is $\|a\|_{2,\tau} = \tau(a^*a)^{1/2}$ for $a \in A$.

On a II$_1$ factor with its unique trace, this gives the *-strong operator topology on bounded sets.

We will get the Rokhlin property for actions of finite groups on factors of type II$_1$ by replacing the usual norm with $\| \cdot \|_{2,\tau}$.

The Rokhlin property and factors of type II$_1$

Let $G$ be finite. $\alpha : G \to \text{Aut}(A)$ has the Rokhlin property if for every finite set $F \subset A$ and every $\epsilon > 0$, there are projections $e_g \in A$ for $g \in G$ such that:

1. $\|\alpha_g(e_h) - e_{gh}\| < \epsilon$ for all $g, h \in G$.
2. $\|e_g a - ae_g\| < \epsilon$ for all $g \in G$ and all $a \in F$.
3. $\sum_{g \in G} e_g = 1$. (In particular, the $e_g$ are orthogonal.)

$\|a\|_{2,\tau} = \tau(a^*a)^{1/2}$.

Definition

Let $G$ be a finite group, and let $\alpha : G \to \text{Aut}(M)$ be an action of $G$ on a II$_1$ factor $M$ with tracial state $\tau$. Then $\alpha$ has the Rokhlin property if for every finite set $F \subset M$ and every $\epsilon > 0$, there are mutually orthogonal projections $e_g \in M$ for $g \in G$ such that:

1. $\|\alpha_g(e_h) - e_{gh}\|_{2,\tau} < \epsilon$ for all $g, h \in G$.
2. $\|e_g a - ae_g\|_{2,\tau} < \epsilon$ for all $g \in G$ and all $a \in F$.
3. $\sum_{g \in G} e_g = 1$. 
The tracial Rokhlin property and factors of type II$_1$

$G$ is finite, and $A$ is simple, unital, and has “enough” tracial states. $\alpha : G \to \text{Aut}(A)$ has the tracial Rokhlin property if for every finite set $F \subset A$ and every $\varepsilon > 0$, there are mutually orthogonal projections $e_g \in A$ for $g \in G$ such that:

1. $\|\alpha_g(e_h) - e_{gh}\| < \varepsilon$ for all $g, h \in G$.
2. $\|e_g a - ae_g\| < \varepsilon$ for all $g \in G$ and all $a \in F$.
3. $\tau\left(1 - \sum_{g \in G} e_g\right) < \varepsilon$.

$\|a\|_{2,\tau} = \tau(a^*a)^{1/2}$.

For the Rokhlin property on II$_1$ factors, we replaced $\|\cdot\|$ with $\|\cdot\|_{2,\tau}$. The analog of the tracial Rokhlin property is then the same as the Rokhlin property. Reason: $e = 1 - \sum_{g \in G} e_g$ has the property that $\|e\|_{2,\tau}$ is small. So we can replace $e_1$ with $e_1 + e$ and leave $e_g$ alone for other values of $g$.

Now $\sum_{g \in G} e_g = 1$, and $\|\alpha_g(e_h) - e_{gh}\|_{2,\tau}$ and $\|e_g a - ae_g\| < \varepsilon$ are still small. So $\alpha$ has the Rokhlin property.

Going between C*-algebras and von Neumann algebras

$G$ is finite. C* tracial Rokhlin property for $\alpha : G \to \text{Aut}(A)$:

1. $\|\alpha_g(e_h) - e_{gh}\| < \varepsilon$ for all $g, h \in G$.
2. $\|e_g a - ae_g\| < \varepsilon$ for all $g \in G$ and all $a \in F$.
3. $\tau\left(1 - \sum_{g \in G} e_g\right) < \varepsilon$.

Rokhlin property for $\alpha : G \to \text{Aut}(M)$ for a II$_1$ factor $M$:

1. $\|\alpha_g(e_h) - e_{gh}\|_{2,\tau} < \varepsilon$ for all $g, h \in G$.
2. $\|e_g a - ae_g\|_{2,\tau} < \varepsilon$ for all $g \in G$ and all $a \in F$.
3. $\sum_{g \in G} e_g = 1$.

Outer actions on factors of type II$_1$

$\|a\|_{2,\tau} = \tau(a^*a)^{1/2}$.

$G$ is finite, and $M$ is a II$_1$ factor with tracial state $\tau$. $\alpha : G \to \text{Aut}(M)$ has the Rokhlin property if for every finite set $F \subset M$ and every $\varepsilon > 0$, there are projections $e_g \in M$ for $g \in G$ such that:

1. $\|\alpha_g(e_h) - e_{gh}\|_{2,\tau} < \varepsilon$ for all $g, h \in G$.
2. $\|e_g a - ae_g\|_{2,\tau} < \varepsilon$ for all $g \in G$ and all $a \in F$.
3. $\sum_{g \in G} e_g = 1$.

Theorem (Jones)

Let $M$ be the hyperfinite factor of type II$_1$, and let $\alpha : G \to \text{Aut}(M)$ be an action of a finite group $G$ on $M$. Then $\alpha$ has the Rokhlin property if and only if $\alpha$ is pointwise outer (for every $g \in G \setminus \{1\}$, $\alpha_g$ is not inner).

This is not true for some other II$_1$ factors. (The von Neumann algebras of free groups have no Rokhlin actions.)

We have also seen that the C* analog is not true even for simple unital AF algebras.

Going between C*-algebras and von Neumann algebras

Let $A$ be a simple unital C*-algebra with tracial rank zero and a unique tracial state $\tau$. Let $G$ be a finite group. Then $\alpha : G \to \text{Aut}(A)$ has the C* tracial Rokhlin property if and only if $\overline{\alpha} : G \to \text{Aut}(\pi(A)''')$ has the von Neumann algebraic Rokhlin property.

Take $G = \mathbb{Z}_p$ with $p$ prime. Then there are four possibilities:

1. $\alpha$ has the Rokhlin property.
2. $\alpha$ has the tracial Rokhlin property but not the Rokhlin property.
3. $\alpha$ is pointwise outer but does not have the tracial Rokhlin property.
4. $\alpha$ is inner.

In the first two cases, $\overline{\alpha}$ is outer and has the Rokhlin property. In the last two cases, $\overline{\alpha}$ is inner. All four cases can occur.

Theorem (with Echterhoff, Lück, and Walters)

Let $A$ be a simple unital C*-algebra with tracial rank zero and a unique tracial state $\tau$, and let $\alpha : G \to \text{Aut}(A)$ be an action of a finite group $G$ on $A$. Let $\pi_\tau$ be the GNS representation of $A$ obtained from $\tau$. (Thus, $\pi_\tau(A)'''$ is the hyperfinite II$_1$ factor.) Let $\overline{\alpha} : G \to \text{Aut}(\pi_\tau(A)''')$ be the induced action. Then $\alpha$ has the C* tracial Rokhlin property if and only if $\overline{\alpha}$ has the von Neumann algebraic Rokhlin property.

Theorem (Jones)

Let $M$ be the hyperfinite factor of type II$_1$, and let $\alpha : G \to \text{Aut}(M)$ be an action of a finite group $G$ on $M$. Then $\alpha$ has the Rokhlin property if and only if $\alpha$ is pointwise outer (for every $g \in G \setminus \{1\}$, $\alpha_g$ is not inner).

This is not true for some other II$_1$ factors. (The von Neumann algebras of free groups have no Rokhlin actions.)

We have also seen that the C* analog is not true even for simple unital AF algebras.
