

Sulfur (S)

REFERENCE STATE

 $A_f = 32.06$ Sulfur (S) $S_1(\text{ref})$

0 to	368.3	K crystal, alpha
368.3 to	388.36	K crystal, beta
388.36 to	882.117	K liquid
above	882.117	K ideal diatomic gas (see below)

The normal boiling point of sulfur at 1 atm, 717.824 K, is a secondary standard on the International Practical Temperature Scale of 1968. The vapor composition at this temperature is a mixture of several sulfur species, the predominant species being $S_1(g)$, $S_2(g)$, and $S_6(g)$. In our reference state for sulfur, we have arbitrarily chosen 0.5 $S_2(g)$ to be the gas phase species.

Sulfur, Monoclinic (S)**CRYSTAL(β)** **$A_r = 32.06$ Sulfur, Monoclinic (S)** **$S_1(\text{cr})$**

$$\begin{aligned} S^\circ(298.15 \text{ K}) &= 33.028 \pm 0.050 \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1} \\ T_m &= 368.3 \pm 0.3 \text{ K } (\alpha-\beta) \\ T_{fs} &= 388.36 \pm 0.1 \text{ K } (\beta-\text{l}) \end{aligned}$$

Enthalpy of Formation

The enthalpy formation of monoclinic sulfus at 298.15 K is calculated from that of orthorhombic sulfur by adding $\Delta_{\text{cr}}H^\circ$ and the difference is enthalpy, $H^\circ(368.3)-H^\circ(298.15 \text{ K})$, between orthorhombic and monoclinic sulfur.

Heat Capacity and Entropy

Experimentally determined heat capacity values for monoclinic (β) sulfur have been reported by Eastman and McGavock (64.83–376.16 K),¹ West (368–388 K),² and Montgomery (12.41–386.83 K).³ The thermochemical functions tabulated by Hultgren *et al.*⁴ are based on work of Eastman and McGavock¹ and West.²

We adopt the heat capacity values tabulated (in 10 K increments) by Montgomery.³ The heat capacity values above $T_{fs} = 388.36 \text{ K}$ are obtained by linear extrapolation of the tabulated heat capacity values³ above 360 K. Using $S^\circ(10 \text{ K}) = 0.063 \text{ cal}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$ and integrating the heat capacity values, we calculate $S^\circ(298.15 \text{ K}) = 7.893 \text{ cal}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$. The $S^\circ(10 \text{ K})$ value contains a contribution of 0.007 $\text{cal}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$ which is needed to make $S^\circ(S, \text{cr}, \beta, T) = S^\circ(S, \text{cr}, \alpha, T) + \Delta_{\text{cr}}H^\circ/T_m$. Since both forms of sulfur are perfectly ordered crystals at 0 K,³ the $S^\circ(0 \text{ K})$ value should be zero, by definition. The contribution of 0.007 $\text{cal}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$ is arbitrarily added at 10 K although it could appear in any temperature region at or below 368.3 K. Part of this entropy may be in the region of the lambda anomaly at 198.3 K. This contribution is comparable to the uncertainty expected from this adiabatic calorimeter.

Phase Data

The $\alpha-\beta$ transition at 368.3 K is discussed on the orthorhombic sulfur table.⁵ The heat capacity data of Montgomery³ did not support the transition at 374 K reported by West.²

Montgomery³ reported a λ anomaly in the heat capacity of monoclinic sulfur with a peak at 198.3 K. The entropy change in the lambda anomaly was $0.052 \pm 0.005 \text{ cal}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$, this was interpreted as due to the disordering of the structure of monoclinic sulfur on heating.⁷

Fusion Data

The melting of sulfur has been studied by many workers. An excellent review by Meyer⁸ summarizes these studies. In addition, Hultgren *et al.*⁴ tabulated numerous enthalpy of melting determinations. We adopt the results obtained by Montgomery³ via adiabatic calorimetry: $T_m = 388.36 \pm 0.02 \text{ K}$ and $\Delta_{\text{fs}}H^\circ = 0.4128 \pm 0.0006 \text{ kcal}\cdot\text{mol}^{-1}$. The only other precise study reported in the literature is that of West² who obtained $\Delta_{\text{fs}}H^\circ = 0.41051 \pm 0.0005 \text{ kcal}\cdot\text{mol}^{-1}$ by adiabatic calorimetry.

Sulfur, Orthorhombic (S)**CRYSTAL(α)** **$A_r = 32.06$ Sulfur, Orthorhombic (S)** **$S_1(\text{cr})$**

$$S^\circ(298.15 \text{ K}) = 32.056 \pm 0.050 \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$$

$$T_m = 368.3 \pm 0.3 \text{ K } (\alpha-\beta)$$

$$\Delta_f H^\circ(0 \text{ K}) = 0 \text{ kJ}\cdot\text{mol}^{-1}$$

$$\Delta_f H^\circ(298.15 \text{ K}) = 0 \text{ kJ}\cdot\text{mol}^{-1}$$

$$\Delta_{\text{tr}} H^\circ = 0.4004 \pm 0.0029 \text{ kJ}\cdot\text{mol}^{-1}$$

Enthalpy of Formation
Zero by definition.**Heat Capacity and Entropy**

Experimentally determined heat capacity values for orthorhombic (α) sulfur have been reported by Nernst,¹ 23–202 K, Eastman and McGavock,² 12.68–365.60 K, West,³ 2981–368 K, Mal'tsev and Demidenko,⁴ 53–305 K, Finke,⁵ 12–432 K, Montgomery,⁶ 12.34–360.99 K, and Paukov.⁷ The thermochemical functions tabulated by Hultgren *et al.*⁸ are based primarily on the work of Eastman and McGavock² and unpublished work of Finke,⁵ the latter presumably being the preliminary results of Montgomery.⁶ The tentative values reported by CODATA⁹ for $S^\circ(298.15 \text{ K})$ and $H^\circ(298.15 \text{ K}) - H^\circ(0 \text{ K})$ are based on Eastman and McGavock,² Montgomery,⁶ and Paukov.⁷

We adopt the heat capacity values tabulated (in 10 K increments) by Montgomery.⁶ Using $S^\circ(10) = 0.036 \text{ cal}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$ and integrating the heat capacity values, we calculate $S^\circ(298.15 \text{ K}) = 7.661 \text{ cal}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$, in agreement with CODATA⁹. The heat capacity values above $T_m = 368.3 \text{ K}$ are obtained by linear extrapolation of the tabulated values⁶ above 340 K.

The various heat capacity studies are in reasonably good agreement. The values recommended by Eastman and McGavock,² West,³ and Mal'tsev and Demidenko⁴ agree with Montgomery⁶ to within 0.5% except for the ranges 15–50 K² and 53–80 K.³ The smoothed value at 190 K reported by Mal'tsev and Demidenko⁴ is undoubtedly a typographical error. The selected values of Hultgren *et al.*⁸ agree within 0.5% with the data of Montgomery⁶ except below 35 K.

Fusion Data

The orthorhomic–monoclinic (α – β) phase change has been studied by many workers. An excellent review by Meyer¹⁰ summarizes these studies. We adopt the results obtained by Montgomery⁶ via adiabatic calorimetry: $T_m = 368.3 \pm 0.3 \text{ K}$ and $\Delta_{\text{tr}} H^\circ = 0.0957 \pm 0.0007 \text{ kcal}\cdot\text{mol}^{-1}$. The only other precise study reported in the literature is that of West³ who obtained $\Delta_{\text{tr}} H^\circ = 0.0960 \pm 0.0005 \text{ kcal}\cdot\text{mol}^{-1}$ by adiabatic calorimetry. Other drop calorimetric^{11,12} and vapor pressure^{13,14} studies are much less precise with an uncertainty of $\pm 5 \text{ cal}\cdot\text{mol}^{-1}$ or greater.

Sublimation Data

Since the reference state of sulfur involves 0.5 $S_2(g)$ rather than $S(g)$, we define the enthalpy of sublimation (at 298.15 K) of orthorhombic sulfur as the process $S(\text{cr}, \alpha) = 0.5 S_2(g)$. Thus the enthalpy of sublimation of orthorhombic sulfur is one-half the enthalpy of formation of $S_2(g)$. Since the dominant gaseous sulfur species at room temperature is actually $S_2(g)$, the enthalpy of sublimation to the equilibrium gas is significantly smaller.

Sulfur, Orthorhombic (S) **$S_1(\text{cr})$**

Sulfur (S)**LIQUID** **$A_r = 32.06$ Sulfur (S)** **$S_1(l)$**

$$S^\circ(298.15\text{ K}) = [36.825] \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$$

$$T_m = 432.02 \pm 0.2 \text{ K}$$

$$T_{fus} = 388.36 \pm 0.2 \text{ K}$$

$$\Delta_f H^\circ(298.15\text{ K}) = [1.854] \text{ kJ}\cdot\text{mol}^{-1}$$

$$\Delta_{fus} H^\circ = 0 \text{ kJ}\cdot\text{mol}^{-1}$$

$$\Delta_{fus} H^\circ = 1.7272 \pm 0.0025 \text{ kJ}\cdot\text{mol}^{-1}$$

Enthalpy of Formation

The enthalpy of formation of liquid sulfur at 298.15 K is calculated from that of monoclinic sulfur by adding $\Delta_{fus} H^\circ$ and the difference in enthalpy, $H^\circ(388.6\text{ K}) - H^\circ(298.15\text{ K})$, between the monoclinic crystal and the liquid.

Heat Capacity and Entropy

The adopted heat capacity values are based on the studies by Montgomery,⁴ 05.79–433.31 K) and West (373–678 K).² Liquid sulfur undergoes a second order transition with a maximum reported at $432.02 \pm 0.20 \text{ K}$ ¹ and $432.25 \pm 0.30 \text{ K}$ ²; this has been attributed to the depolymerization of S_8 molecules.³ We adopt the tabulated heat capacity values of Montgomery¹ up to 434 K and those of West² above 434 K. The heat capacity is assumed to be constant at $7.568 \text{ cal}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$ above 810 K. Below $T_m = 388.36 \text{ K}$, the heat capacity values are obtained by linear extrapolation using the slope of the values in the region T_m to 420 K. The entropy at 298.15 K is calculated in a manner analogous to that used for the enthalpy of formation.

Vaporization Data

The normal boiling point of sulfur, $T_{vap}(1 \text{ atm}) = 717.834 \text{ K}$ is a secondary reference on the International Practical Temperature Scale of 1968. At this temperature, equilibrium sulfur vapor contains monomeric and several polymeric sulfur species: $S_2(g)$ and $S_4(g)$ predominate above 1000 K while $S_6(g)$, $S_7(g)$ and $S_8(g)$ dominate at T_{vap} .

Since our reference state for sulfur is arbitrarily defined to involve 0.5 $S_2(g)$ as the vapor species, we calculate the arbitrary normal boiling point, $T_{vap}(1 \text{ bar})$, for the process $S(l) \rightarrow 0.5 S_2(g)$. The brackets are used to indicate the arbitrary nature of this value. Since we only consider $S_2(g)$ in this vaporization, note that the boiling point is considerably different from the secondary reference IPTS value. If all n-mers of sulfur are considered in the vaporization process, then a normal boiling point (1 atm) is closely reproduced.

Enthalpy of Formation

The enthalpy of formation is based on the dissociation energy for S₂(g) as recommended by CODATA.¹ The adopted value for $\Delta_f H^\circ(S, g, 298.15 \text{ K})$ is calculated using $D_0^0(S_2) = 35216.4 \pm 2.5 \text{ cm}^{-1}(421.282 \pm 0.03 \text{ kJ}\cdot\text{mol}^{-1})$ from the study of Ricks and Barrow.²

The selected dissociation energy, obtained from precise spectroscopic measurements,² is supported by additional studies on thermochemical cycles,³ photoionization^{4,5} and torsion-effusion measurements.⁶ Earlier measurements have been reviewed by Herzberg,⁷ Gaydon,⁸ Brewer,⁹ and Drowart and Goldfinger.³

Heat Capacity and Entropy

The electronic levels for S(g) are given in the compilation by Moore.^{10,11} Our calculations indicate that, except for the five levels lying below 23000 cm⁻¹, the inclusion of levels up to $n = 10$ has no effect on the thermodynamic function to 6000 K. This is a result of the high energy of these levels; the fifth excited state lies at 52623.88 cm⁻¹ above the ground state. Since the inclusion of these upper levels has no effect on the thermodynamic function (to 6000 K) we list only the lowest lying states ($\epsilon < 23000 \text{ cm}^{-1}$). The reported uncertainty is $S^\circ(298.15 \text{ K})$ is due to uncertainties in the relative atomic mass and the fundamental constants. Extension of these calculations above 6000 K may require consideration of the higher excited states and utilization of proper fill and cutoff procedures.¹² In fact, the inclusion of these higher excited states and consideration of various cutoff procedures leads to calculational differences in the Gibbs energy function of $\sim 0.4 \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$ or greater at temperatures in excess of 11500 K. The thermal functions at 298.15 K agree with CODATA recommendation¹ except for two minor differences. First, the entropy differs by $0.1094 \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$ because this table uses a standard state pressure of 1 bar, whereas the CODATA recommendations are based on 1 atm. Second, an entropy difference of $0.004 \text{ J}\cdot\text{K}^{-1}\cdot\text{mol}^{-1}$ arises due to the use of slightly different values for the fundamental constants.
